VISUAL REQUIREMENT IN THE PUBLIC SERVICES OF THE UNITED STATES*

WILLIAM CAMPBELL POSEY, M.D.
PHILADELPHIA

I invite your attention to the consideration of the visual standards in the public services of the United States, the subject concerning which I have chosen to address you this afternoon. It occurred to me that it might be well to collate all the laws which the government has enacted regarding the visual requirements of those engaged in its public services. I was aware that this information had never been collected and placed in a readily accessible form, as I had frequently myself had difficulty in ascertaining what the standards of vision were, which governed the admission of cadets into our naval and military academies, or regulated the granting of licenses to pilots.

With this idea in mind, and with the intention of laying the entire subject before the Section at this meeting, I devoted myself to the acquisition of as much information regarding the matter as was possible, and in addition to studying the conditions at home, communicated with foreign governments through the cooperation of our embassies, and obtained from Great Britain, Germany and France, the visual standards which these countries enforce in their various services.

With the data of these investigations at hand and with all the information on the subject which I could command, I determined before proposing any modifications or changes in existing standards to endeavor to elicit the aid and cooperation of the officers of the various branches of the public services themselves, realizing that while we, as practicing and scientific ophthalmologists, might be more familiar with certain phases of the subject, they for their part, by virtue of long experience, were better fitted than we to decide on certain points. With this end in view, I had an interview with the Surgeon-General of the Army, Dr. George H. Torney, and was much pleased to have not only his entire approval of my plan, but also his offer of full cooperation. Indeed, he suggested that I proceed at once to draft a new series of visual requirements for the Army, and that this revision of the standards might be comprehensive and in a manner authoritative, he suggested that I associate with me the three ophthalmologic members of the Medical Reserve Corps of the Army, Drs. L. Webster Fox and George E. deSchweinitz, of Philadelphia,

and Dr. Myles Standish, of Boston, nominating me also to a lieutenantancy in the same Department. All three of these gentlemen expressing their willingness to cooperate, the Philadelphia members, Drs. Fox, de Schweinitz and myself, invited a number of army officers who were resident in Philadelphia at the time, and several prominent members of the Pennsylvania National Guard to meet us, for the purpose of obtaining from them their ideas regarding the degree of vision which was necessary for the proper performance of the duties of a soldier or officer in the various fields of army activity. The demands on sight in each corps of the army were considered very carefully and the views of all of the gentlemen present, who represented nearly all the departments of the army, were carefully noted.

The various communications on the subject which had been addressed to the War Department from time to time by officers and surgeons of the army, relative to vision were also studied, and mention must here be made of the indebtedness of the commission to the admirable report¹ of Lieut.-Col. J. M. Banister, and Major H. A. Shaw, made in October, 1909, from which much valuable information was obtained regarding the degree of vision necessary for the enlisted man.

The visual standards in operation in the armies of Great Britain, Germany and France were next studied and consideration given to the probable reasons for their variations from our standards. With this information drawn from such wide and varied sources at hand, the commission drafted a series of requirements of its own. These have received the approval of the Surgeon-General of the Army and will shortly be submitted by him to the general staff for adoption.

PRESENT REQUIREMENTS IN THE ARMY

The present requirements, with dates of adoption for the various corps and departments attached are as follows:

U. S. MILITARY ACADEMY—ADMISSION

"Vision, as determined by the official test-types, must not fall below 20/40 in either eye, and not below 20/20 unless the defect is a simple refractive error not hyperopia, is not due to ocular disease, and is entirely corrected by proper glasses.

"In the record of all examinations, the acuity of vision without glasses, and also with glasses when the acuity is less than 20/20, will be given for each eye separately; in the latter case the correction will also be noted.

"Hyperopia requiring any spherical correction, anisometropia, squint or muscular insufficiency, if marked, are causes for rejection.

"Color-blindness, red, green or violet, is cause for rejection."
G. O. 176, '06.

" . . . In the examination of cadets, except those on probation, discharge will not be recommended except for some cause which disqualifies for the duties of a cadet or is likely in the future to impair his efficiency as an officer of the Army.

* Chairman's address before the Section on Ophthalmology of the American Medical Association, at the Sixty-first Annual Session, St. Louis, June 7-10, 1910.

* The length of this address made necessary its abbreviation in THE JOURNAL. The introductory remarks are omitted, in which Dr. Posey commented on some of the features of the program for this session. Some of the details of the descriptions of various visual tests are also omitted further on in the article. The complete text appears in the Transactions of the Section and in the author's reprints.

Defects of vision, however, must in all cases be entirely corrected by glasses." G. O. 176, '06.

SECOND LIEUTENANT FROM CIVIL LIFE

The visual requirements are satisfied by a candidate who has "20/40 in either eye, or who is not color-blind for red, green or violet." G. O. 59, '08.

MEDICAL CORPS

"Errors of refraction, if not below 20/40 in either eye, are not cause for rejection, provided they are not accompanied by ocular disease and are entirely corrected by appropriate glasses."

HOSPITAL CORPS

"Applicants may be accepted with a vision of 20/70 in either eye, correctible to 20/40 with glasses, provided that no organic disease exists in either eye." G. O. 256, '07.

ENLISTED MEN OF THE LINE

Enlisted men of the line of the Army and of the Engineer and Signal Corps, a minimum of 20/40 for the better eye, and of 20/100 for the poorer, provided that no organic disease exists in either eye.

Enlisted men of the Ordnance, Subsistence and Quartermaster's Departments and for the Hospital Corps a minimum of 20/70 in each eye correctible to 20/40 with lenses, provided that no organic disease exists in either eye.

Recruits may be accepted for the line of the Army when unable with the better eye to recognize all of the letters on the 20/40 line, provided that they may be able to read some of the letters on the 20/30 line. Circulars 4 and 5, 1908.

Reference to the "better eye" in the preceding requirements indicates the right eye, it having been determined that shooting from the left shoulder is undesirable.

PROPOSED REQUIREMENTS

The proposed requirements which have been presented by the commission appointed by General Torney are as follows:

I. REQUIREMENTS IN THE U. S. MILITARY ACADEMY

For Entrance.—A minimum of 6/6 vision in each eye. If hypermetropia be present, as detected by the test lenses, a manifest of more than 1 D. will exclude. The muscle error at 6 meters shall not exceed a hyperphoria of 2°, an exophoria of 5°, or an esophoria of 8°. Color-blindness, red, green or violet, is cause for rejection.

For Graduation.—A minimum of 6/12 vision in one eye and of 6/18 in the other, but capable of being corrected to 6/6 in each eye by proper lenses, is requisite.

ADDENDA

Examination shall be made of the eyes of all cadets at the commencement of each academic year and if at any time during the course vision is found to have deteriorated to a degree greater than is required at graduation, the cadet shall be dropped. When a refraction error exists, cadets shall be commanded to wear the glasses prescribed for them precisely as directed by the medical officer in charge.

II. SECOND LIEUTENANT FROM CIVIL LIFE

A minimum of 6/12 in one eye, and of 6/18 in the other, capable of correction in each to 6/6, and a normal color sense are requisite. The muscle error at 6 meters shall not exceed a hyperphoria of 2°, an exophoria of 5°, or an esophoria of 8°.

III. FOR PROMOTION

For advancement through the various grades short of that of major, uncorrected vision must equal at least 6/24 in one eye and 6/30 in the other, and corrected vision, 6/6 in one eye and 6/12 in the other. For promotion to the rank of major and all higher grades no definite visual standard is required. The eyes, however, shall be carefully examined in each case, and if in the opinion of the Examining Board their condition is such that they render the performance of the military duties peculiar to each rank impossible, the officer shall be recommended for retirement.

IV. MEDICAL CORPS

For Entrance.—A minimum of 6/18 is requisite in each eye, which is capable of improvement to 6/6.

For Promotion.—Uncorrected vision shall not fall below 6/30 in one eye and 6/60 in the other, and corrected vision shall equal 6/6 in one eye.

V. HOSPITAL CORPS

For entrance and promotion, a minimum of 6/21 is requisite in either eye, which is capable of improvement to 6/6 in one eye and at least 6/12 in the other.

VI. ENLISTED MEN OF THE LINE OF THE ARMY AND OF THE ENGINEER AND SIGNAL CORPS

A minimum of 6/12 for the better eye and of 6/30 for the poorer is requisite.

VII. ENLISTED MEN OF THE ORDNANCE, SUBSISTENCE AND QUARTERMASTER'S DEPARTMENTS AND OF THE HOSPITAL CORPS

A minimum of 6/21 for the better eye, and 6/30 for the poorer is requisite, correctable to 6/6 and 6/12, respectively.

OTHER CAUSES FOR REJECTION

Apart from the visual standards which have just been described, and the restrictions as to muscle error and defects in the color-sense imposed in certain branches of the service, the presence of any structural changes or inflammatory conditions of the eyeball or its adnexa, such as might lead to impairment of vision later, are causes for rejection in all departments of the Army. Candidates whose eyes present merely the results of former inflammatory processes, may be accepted, provided the eyes are entirely free from inflammation at the time of the examination, and that they possess the necessary degree of vision, and that the sequelæ of the previous inflammation have entailed no serious impairment in the structure of the eye or its adnexa.

DIRECTIONS FOR CARRYING OUT THE TESTS

In testing the degree of visual acuity and of the balance of the extraocular muscle, the candidate must be seated exactly at 6 meters from the charts and the light used in the muscle test, and this distance must never be varied. (Six meters shall be regarded as equivalent to 20 feet.)

For purposes of uniformity and to guard against the possibility of any deception on the part of the candidates, all tests shall be made with the standard charts issued by the department. These shall be exhibited to the candidate in a good natural or artificial light at a height of 4 or 5 feet from the ground. In the tests made at the Military Academy, the charts shall be illuminated by the Williams battery of electric globes, with daylight excluded from the room.

Each eye shall be tested separately and the examiner must exercise the greatest caution that the eye which is not under examination shall be properly excluded. During the performance of the test the lids must remain naturally open, squinting being prohibited. In the event that the candidate is unable to read all the letters on the line designated as his minimum vision, he will be passed, provided he is able to read three of the letters on the next smaller line with both eyes directed on the chart.

The manifest hypermetropia shall be detected by testing each eye separately, either by the so-called fogging system of first holding a + S. 3 D. or 4 D. lens before the eye and then gradually abstracting from its strength by holding — S. lenses before it until 6/6 vision is attained, or by beginning with + S. 0.25 D. and gradually increasing the strength of the lens until the letters on the 6/6 line are no longer visible.

The muscles of candidates at the Military Academy and of second lieutenants from civil life shall be tested with the Maddox rod, and a set of prisms. Their color-sense shall be ascertained by the tagged Holmgren worsted test-of-Williams.

L. WEBSTER FOX,

GEORGE E. DE SCHWEINITZ,

MYLES STANDISH,

WILLIAM CAMPBELL POSEY, Chairman,

Lieutenants Medical Reserve Corps, Feb. 11, 1910.

In our letter of explanation to the Surgeon-General, of the proposed standards and tests which we offered the commission wrote as follows:

The requirements at the Military Academy have been raised so that each candidate must have full visual acuity. This has been done for a variety of reasons. In the first place, it is believed that there will be no difficulty in obtaining a sufficient number of candidates from young men who possess full vision, as observation has shown that at least 65 per cent. of the young men who enter American colleges have normal sight in both eyes. If a lower degree of visual acuity is accepted, a number of candidates with myopia and astigmatism will be received into the department, whose sight will still further deteriorate under the strain of student life while they are in the Military Academy, as well as in the service later, as a consequence of the tax placed on the eyes by the increasing amount of study demanded of officers for promotion through the various grades. The elimination of candidates with high degrees of hypermetropia by the rejection of those possessing more than 1 D. of manifest hypermetropia, as well as of those with troublesome degrees of muscle errors, has been advised with a view to debarring from the service all who would be likely to suffer from eye-strain under the demands of prolonged study.

It has been deemed wise to establish a standard for graduation, in order that the department may have an authoritative basis for retiring a cadet when the eyes had deteriorated to such an extent that his usefulness as an officer might be curtailed, but the commission has purposely set the standard so low that only those whose eyes had deteriorated to an unusual degree would be debarred from graduation. It is believed that a minimum of 6/12 in one eye and of 6/18 in the other, capable of improvement in each eye to 6/6, will not exclude cadets who may develop the moderate amount of myopia which is natural at their age among all students employing their eyes under somewhat similar conditions.

It is advised that the medical officer in charge of the Academy should make ocular examinations of all the cadets at least once a year and should carefully test under atropin all those with symptoms of asthenopia or whose eyes manifest any tendency toward deterioration. Glasses should be worn constantly if judged necessary.

In order to avoid deception on the part of the candidates, it is recommended that the department prepare its own charts, on which such devices and letters may be figured as will not lend themselves to be easily learned by the candidates.

At West Point, where it is most desirable that all of the tests should be made under uniform conditions, a standard means of illuminating the test cards has been suggested, and the committee recommends that devised by Dr. Charles H. Williams, of Boston, for this purpose.

A candidate for a second lieutenancy from civil life is given the same visual requirements as obtain for graduates from the Military Academy.

Candidates for entrance into the Medical Corps are permitted to possess a somewhat lower degree of visual acuity than under the old standards, i. e., 6/18 instead of 6/12, while the same standard is maintained for the Hospital Corps, though improvement of the vision in one eye to normal is deemed requisite.

The former standard for enlisted men of the line of the Army has been maintained, as it is the opinion of the committee that while the possession of the minimum degree would be insufficient for sharpshooting and the performance of other duties which demand the sharpest vision, there would always be a sufficient number of candidates enlisting with normal vision from whom there would be no difficulty in securing soldiers who would be able to perform the duties demanding extraordinarily sharp vision.

It is not possible to dwell further at this time on the eyes of the soldier, but to those who may be surprised at the comparatively low standard which has been set for the enlisted man, it may be said that modern warfare has abolished in large measure the need of sharp vision, and that with the exception of sharpshooting, firing at the enemy is done in volleys at definite ranges, which is determined by the officers in charge and is irrespective of definite aim at any one object.

THE MERCANTILE MARINE PILOTS

There are two classes of pilots in the United States.

1. *Federal Pilots.*—Under this class is comprised masters, mates and pilots of all steam vessels and the masters of sail vessels of over 700 gross tons, and all other vessels of over one hundred gross tons carrying passengers for hire.

2. *State or Bar Pilots.*—These branch pilots, as they are frequently termed, are under state law or municipal regulation. They lie off the principal harbors and bring in and take out vessels in the foreign trade and in some states sail-vessels in the domestic or coasting trade. They are in no way amenable to the federal government, but are under the supervision of the pilot commissioners or bureaus of navigation of the various states.

FEDERAL PILOTS

According to act of Congress (Sections 4439, 4440, 4442 of the Revised Statutes of the United States), "No original license as master, mate, or pilot of any vessel propelled in whole or in part by steam, gas, fluid, naphtha, alco-vapor, electric, or other like motors, or master or mate of sail vessels, shall be granted except on the official certificate of a surgeon of the Public Health and Marine-Hospital Service, that the applicant is free from the defect known as color-blindness. No renewal of license shall be granted to any officer of the classes named who has not been previously examined and passed for color-blindness: *Provided, however,* That any person that received a license prior to the adoption of the rule demanding a visual examination may have such license renewed for daylight navigation only, provided there is no other bar to such renewal: *Provided, further,* That any person holding a license as mate on steamers navigating waters flowing into the Gulf of Mexico and their tributaries issued prior to 1905 may have such license renewed without being subjected to the examination for color-blindness.

"Any person requiring examination for color-blindness who is living at a distance of 100 miles or more from a surgeon of the Public Health and Marine-Hospital Service may be examined for color-blindness by any reputable physician; and the physician shall furnish a duplicate report of the examination made on the regulation blanks, one copy of which shall be furnished the applicant and the other sent to the local inspectors of steam vessels to whom the applicant shall apply for such original or renewal of license."

The first test for color-blindness in the U. S. Marine dated from an order from the Treasury Department to Supervising and Local Inspectors of Steam Vessels as early as 1880. The wording of the decree was as follows:

By an amendment to Rule 47, Rules and Regulations of the Board of Supervising Inspectors, adopted at the twenty-eighth session of the Board, recently held in this city [Washington], and which was approved by the Secretary of the Treasury, Feb. 13, 1880, and promulgated in Department Circular No. 13, 1880, it was ordered that all persons applying for either a renewal of license, or an original license, as pilots on steam-vessels, shall be required to undergo a visual examination, in order that it may be determined whether such person can properly distinguish the colored lights used as signals on steam-vessels; and, in future, inspectors will issue pilots' licenses only on certificates of surgeons of the United States Marine-Hospital Service that applicants therefor fulfil all the requirements of the rule referred to.

Under the provisions of Department Circular of June 11, 1879, surgeons of the Marine-Hospital Service are directed to make such examinations free of expense to persons applying therefor.

In pursuance of this order the Marine-Hospital Service in 1903 enacted the following (paragraph 119):

Whenever officially requested by the local inspectors of steam-vessels or other proper officials, commissioned officers will examine applicants for pilots' license as to sense of hear-

ing, color perception and general visual capacity, and will give a certificate accordingly.

In Instructions Relative to Physical Examinations (paragraph 15) the following instructions are given:

The eyesight will be tested by the test-types furnished by the Bureau, and the Holmgren worsted test will be employed in testing for color-sense. The test must be made for each eye separately.

LACK OF A FIXED STANDARD

It will be seen, from the foregoing that the federal government has recognized the importance of the color test for a considerable length of time and has enacted sufficient legislation to debar color-blind navigators from the command and piloting of many vessels. It has, however, failed to designate the degree of visual acuity which a candidate for a pilot's or officer's license must possess. The Marine-Hospital Corps, realizing that its officers who make the tests at the request of inspectors of the Department of Commerce and Labor, must have some standard to guide them in their examinations, established an unwritten requirement that vision shall not fall below 15/20 in each eye when tested separately. I have ascertained, however, by extensive inquiry, that many officers of the corps are unaware of the existence of this order, and that those who are cognizant of it do not always adhere to it with absolute literalness.

As at present constituted, the final decision in regard to the acceptance or rejection of a candidate does not reside with the officers of the Marine-Hospital Service, but with the local representatives of the Department of Commerce and Labor, the inspectors of steam-vessels of a port, the officers of the former corps merely transmitting the results of their examination to the inspectors, with a recommendation as to the candidate's fitness or unfitness for the position for which he is applying. The Department of Commerce and Labor having failed to establish a standard, the decision of the degree of vision a navigator must possess before he is granted a license depends entirely, therefore, on the judgment of the Marine-Hospital officer conducting the test, and the opinion of the local inspector.

From what has been said, it is apparent, I think, that the absence of any fixed standard of visual acuity to govern the tests made by the federal government is due to no fault of the Marine-Hospital Service and reflects in no way on the admirable and efficient conduct of that corps. The power to create standards for use in these tests resides entirely in the Department of Commerce and Labor, and I have no doubt but that the present lack of a standard is due to the fact that the officers of that department have never had their attention called to the matter and have not appreciated the actual condition of affairs.

STANDARDS PREPARED FOR SUBMISSION TO THE DEPARTMENT OF COMMERCE AND LABOR

With a view to correcting the evil and to obtaining if possible, a fixed standard of vision on which to base the granting of licenses to navigators under federal law, I visited Washington some months ago and took up the question with General Wyman. This distinguished officer received my overtures with the greatest friendliness and alacrity, and suggested that I submit my ideas of proper standards to him, that he might present them to the Department of Commerce and Labor for consideration and possible adoption.

As I have been much interested in the examination of pilots' eyes for many years, and as official oculist to the Board of Pilot Commissioners of Pennsylvania had just

finished testing the eyes of all the pilots of that state under a new law which the commissioners had put in operation at my instance some months before and which had proved most satisfactory in its operation to commissioners and pilots alike, I ventured to accede to General Wyman's request and to draft a series of standards which were framed along the same lines, to govern the examinations of federal pilots. The standards which have been prepared for the consideration of the Department of Commerce and Labor to govern the examination of federal pilots by the Marine-Hospital Service are as follows:

Normal color-sense is requisite. Any imperfection disqualifies.

A candidate must have at least 20/40 uncorrected vision in one eye and 20/70 in the other, and corrected vision must equal 20/20 in one eye and at least 20/40 in the other.

All pilots under 50 years of age must submit to reexamination every five years; those over 50 years every two years.

In the event that the examiner has reason to suppose that visual acuity or color-sense may rapidly deteriorate, he shall issue a license only for as long a time as he considers the visual standards will be maintained, the candidate being ordered to report for reexamination at the end of that period.

DIRECTIONS TO BE OBSERVED IN MAKING THE TEST FOR VISUAL ACUITY

The examiner will observe that the Snellen charts used in the tests shall be exhibited to the candidate at a height of 4 or 5 feet from the ground and at a distance of 20 feet exactly, and this distance must be maintained throughout the test. A good light must fall on the chart, and during the tests charts with different lettering should be employed in such a manner that the candidate cannot become familiar with the letters on the various lines. Each eye should be tested separately by carefully excluding the eye which is not being examined by holding a card before it. No pressure should be exerted nor should the excluded eye be closed.

As soon as the examiner has ascertained the lowest line which the candidate has been able to read, the vision shall be recorded in the form of a fraction, the numerator of which will represent the distance at which the test was made, i. e., 20 feet, the denominator the number on the chart opposite the last line which was read. The fellow eye is now similarly tested. During the performance of the test, the lids must remain naturally open, squinting being prohibited. In the event that the candidate is unable to read all the letters on the line designated as his minimum vision, he will be passed, provided he is able to read three of the letters on the next smallest line with both eyes directed on the chart.

DIRECTIONS TO BE OBSERVED IN MAKING THE TESTS FOR COLOR-SENSE

The wools should be carefully kept in the boxes provided for the purpose, except when in use in examinations, in order that they may not become faded or dirty.

The test should be made only by daylight and never when the weather is very dark or foggy.

A properly assorted set of wools consists of 3 large test skeins, of a light pure green, rose pink and red, respectively, and of 150 small skeins of the following colors: red, orange, yellow, yellow green, pure green, blue-green, blue, violet, purple, pink, brown and gray. In addition, there are several shades of each color and a number of gradations of each tint from the deepest to the lightest.

Test 1.—After the entire set of wools has been spread out on a table before the candidate, the examiner places the large green test skein at a distance of about two feet from the other colors, and asks the candidate to select from the heap of colors all that look to him like this test skein, and place them beside it. No names should be mentioned in connection with any color in the above-worsted test, which should be based only on a comparison of colors. The candidate should be made to understand that he is not expected to find an exact match for the test skein, but that he is to choose all the colors that appear

to him of the same general color as the test skein, both those that are lighter and those that are darker in shade. If he does not easily understand what is wanted, let the examiner himself select the colors; then, having returned them to the general heap and mixed them thoroughly with the rest of the colors, let him call on the candidate being examined to repeat the selection. This demonstration will not enable a candidate who is defective in his color-perception to select the colors correctly, and he may pick out, as looking to him like the large test skein, some greens and also some of the gray or brown confusion colors, which will appear to him of the same general color as the test skein only varying from it in shade.

A person with a normal color-sense will pick out the lighter and darker shades of green rapidly and without hesitation. He may, perhaps, include in his choice a few green skeins inclining to yellow or blue; but this is no evidence of color-blindness, but rather of a lack of practice with colors. The completely color-blind, whether to red or green, will select, with or without greens, some confusion colors—grays, drabs, stone-colors, fawns, pinks or yellows. The incompletely color-blind, or those with a feeble chromatic sense, will add to the selection of greens one or more light fawns or grays; or they may pick out a skein, hesitate, add it to the greens and then withdraw it, and so on.

When confusion colors have been selected, we know that the candidate is either completely or incompletely color-blind. In order to determine its nature and degree we employ a second test.

Test 2.—Return all the colors to the heap and mix them together. Place the rose test skein apart from the rest, and have the candidate select, as before, all the colors that look to him like this skein.

The color-blind will always select deeper colors, i. e., either the light or deep shades of blue and violet. The completely red-blind will select blue or violet, either with or without purple. The completely green-blind will choose green or gray either with or without purple.

A candidate who is proved color-blind by the first test is only incompletely color-blind if he matches the rose with deeper purples alone.

Test 3.—This test is merely supplementary to the two preceding and consists in separating the red skein from the rest of the wools. The red-blind will select, besides the red, green and brown shades darker than the red. The green-blind will select green and brown shades lighter than the red. Only persons with marked color-blindness manifest their defect with this test.

Williams Lantern Test.—Turn the rheostat so as to have a medium illumination from the two incandescent lights in the lantern, or, if an electric current is not available, light both lamps, taking care not to turn them up so high as to smoke, then place the lantern 20 feet from the person to be examined about on a level with his head, the side of the lantern carrying the disc with the colored glasses directly toward him, and darken the room. Place the shutters so that three lights are shown at one time through either the largest or the medium openings, turn the disc slowly, and have the person examined call aloud the names of the colors as shown, designating them thus, "middle red, right red, left green," etc. Under each color is a distinguishing number which is lighted at the same time as its color, and as the examination proceeds the examiner will note the number of the color shown and the name given to it.

After all the combinations with three colors at a time have been shown, change the shutters so as to show one or two lights at a time and revolve the disc again, noting the results as before.

Calling a green light blue, or *vice versa*, calling a yellow red, or, with the smallest opening failing to see the color of No. 7 (cobalt blue) which transmits less light than some of the others, will not be considered serious mistakes, but the confusion of red or green with each other will reject.

UNLICENSED PILOTS

According to the present law, there are a large number of vessels of considerable tonnage whose masters need not necessarily take out a license. Thus, masters of

yachts and of sailing vessels under 700 gross tons and of motor vessels of 15 gross tons or less, and motor vessels, irrespective of tonnage, if not engaged in transporting freight or passengers, are not required to have their eyes tested. As a consequence, there are numerous craft on our waterways which are a continual menace to the safety of navigation, for surely a color-blind pilot of a sailing vessel of less than 700 tons or of a yacht or a large motor boat may be as much a menace to safe navigation as one on a larger vessel! Quite apart from the perhaps comparatively insignificant loss of life and property which might follow an accident to a small vessel, it has not infrequently happened that large vessels have been sent to the bottom as a result of collision with smaller craft and hundreds of lives lost, and millions of dollars worth of property sacrificed by the carelessness or incompetence of the navigators of the smaller boat. As an instance of this may be mentioned the following disaster:

"Feb. 11, 1907: Schooner *Harry Knowlton*, 317 gross tons, bound from City Island, N. Y., to Everett, Mass., coal-laden, collided with and sunk passenger steamer *Larchmont*, en route from Providence, R. I., to New York, in Block Island Sound. Collision occurred about 10:30 p. m. Schooner abandoned. Crew saved. Of *Larchmont's* passengers, 89 (estimated) were lost; also 44 members of the crew. . . ."

The government would do well, it seems to me, if it extended its jurisdiction over all navigators of vessels of any appreciable size.

REVENUE CUTTER SERVICE

In addition to conducting the examinations for federal pilots, the Marine-Hospital Service performs the same duties in connection with the Revenue Cutter Service. This service includes officers, cadets and enlisted men. The present requirements demand normal vision without glasses and normal color perception, for cadets and seamen, but no mention is made of the requirements demanded for promotion or of the repetition of the test; the visual standard for the enlisted men between decks, who are mere firemen or stewards, without the need of sharp vision, are the same as those for the true seamen on deck.

LIFE-SAVING SERVICE

The Navy Department controls the examination also of the Coast Guards. This picked body of men are examined annually and the department demands that they possess normal color sense and 15/20 uncorrected vision in each eye.

COAST AND GEODETIC SURVEY

Candidates for the Coast and Geodetic Survey are also examined by the Marine Hospital Corps, but in this department the Department of Commerce and Labor, under whose secretary the Coast and Geodetic Survey is operated, has not established any definite standards. A recent letter directed to the acting superintendent of the Coast and Geodetic Survey regarding the visual test for candidates into their service, brought the following reply:

When an eligible is certified to this office by the Civil Service Commission for a vacancy on the field force, his medical certificate is considered with the view of ascertaining whether he is physically able to stand the hardships and exposures incident to the field work of this survey. *There is no definite standard and each case is treated separately.* [Italics mine.—W. C. P.] Should there be any doubt as to whether a man is physically fit for our service, he will be required to stand a physical examination before an officer of the Public Health and Marine-

Hospital Service. Such an examination would be in order to get exact data regarding the health of the applicant and the question of whether he was suitable for appointment to this survey would still be decided by this office. You will see from this that the Public Health and Marine-Hospital Service is called on more to give facts in any case than to make a decision.

CIVIL SERVICE COMMISSION

According to a ruling of the U. S. Civil Service Commission, applicants for appointment to positions controlled by that service may procure a medical certificate from any physician, but the applicant may be required to pass a physical examination before an officer of the Marine-Hospital Service before appointment. I have been unable to ascertain that this commission has established any definite physical standards, and infer that the Marine-Hospital officers consider each candidate with a view to his general fitness.

STATE OR BRANCH PILOTS

Under an Act of Congress, of Aug. 7, 1789, it is provided "that all pilots in the bays, inlets, rivers, harbors and ports of the United States shall continue to be regulated in conformity with the existing laws of the states, respectively, wherein such pilots may be, or with such laws as the states may respectively hereafter enact for the purpose, until further legislative provisions shall be made by Congress."

This law is still in force, and as has been already said, these state, bar or branch pilots lay off the principal harbors and bring in and take out vessels in the foreign trade and in some states sailing vessels in the domestic or coasting trade. These pilots are amenable to state law or municipal regulation, and are under the immediate supervision of a board of pilot commissioners, or bureau of navigation. This board or bureau has the power to regulate the service of the pilots as it deems proper. The pilots themselves, however, determine in large measure their membership, recruiting their members very often from their own families, and have formed themselves into associations or unions for their protection and benefit. In popular phraseology, they form "a close corporation," and I have been told by a reliable informant that they employ a skilled lobbyist in Washington, who keeps jealous watch that none of their ancient rights or prerogatives shall be curtailed.

The federal government exercises absolutely no control over them, and there is no record in Washington of the requirements which the various states demand of them.

Being unable to obtain from the central government any information regarding the visual tests which state pilots must submit to before they are given their licenses, I addressed a letter requesting this information to the president of the board of pilot commissioners at each of our principal seaports. The answers received at once revealed that with but few exceptions the commissioners in the various states had failed to enact any definite visual requirements, but that the question of the sight of pilots was left to the pilots themselves. As a rule each pilot must serve an apprenticeship of six years under the personal observation of the active pilots, and it is claimed by the pilot associations of most of the states that by this method all candidates with defects of vision are eliminated, before they are recommended for appointment. In some of the states, and this is particularly true of those on the Pacific slope, the pilot commissioners refer the candidates to the Marine-Hospital Service, and each pilot is required to present a

certificate that he has passed the examination of that department. It is probable that the officers in charge of these tests demand the same requirements as they do of federal pilots.

The important harbor of New York is under the control of both New York and New Jersey pilots. In order that the Section may be informed as to the precise manner in which the pilots for that busy harbor are examined, I shall read the very lucid replies which were sent me by Mr. D. A. Nash, the Secretary of the Board of Commissioners of Pilots of New York:

In examining pilots for eyesight (which is done at least once each year and oftener if occasion seems to call for it) we use the regular test cards of printed letters prepared and used by opticians for that purpose. We also use the buoys in the upper bay (of which a number are visible from this office) and for readiness or quickness of observation the numbers of passing elevated railroad cars, etc., the examiner using a binocular glass to verify the answers where necessary.

For colors we use the system of worsteds as recommended in the work of B. Joy Jeffries.¹

I may add that owing to the custom in vogue here of choosing the candidates for apprenticeship from the young men already working as hands on the pilot-boats, it is not often that a color-blind person or one who is below the normal in eyesight reaches the point of applying for registry as apprentice. They are eliminated before that time arrives.

We are not aware of any special tests demanded by the State of New York.

The only provision of law known to the board relating to the examinations of the eyes of the New York State bar pilots (whom alone we have to deal with) is by-law No. 12, d, as follows:

By-Law 12, d.—"Every candidate shall be examined in the presence of the board as to color-blindness and as to his general eyesight and hearing, and before each renewal of his license to pilot he shall undergo a like examination by the secretary. A pilot considered deficient or doubtful by the secretary shall be referred to the board for final action. A person held to be deficient on the above points by the board shall not be entitled to receive a license."

There are no special oculists who test the eyes of the pilots. If a pilot is not satisfied with the decision of the board, he may go to an oculist of his own choice or to the U. S. Examiners for Steamboat Pilots and submit their report to the board.

The final decision rests with the board, who may or may not agree with the findings of these supplemental examinations.

It will be noted that no definite standard of vision is required and that the tests are made by laymen, the services of an oculist being only resorted to in case of dissatisfaction from an adverse ruling.

The tests for the harbor of Boston are made by the Pilot Commissioners themselves, under the following requirements: The candidates must have "good sight for distances, and must be able to tell the colors of light at a distance."

The Delaware River is under the control of Pennsylvania and Delaware pilots. Until a few months ago the Commissioners of Navigation of Pennsylvania submitted candidates to examination by an oculist, appointed by them, and required that each applicant for a license possessed "good vision and normal color perception." As far as I can learn, therefore, the Pilot Commissioners of Pennsylvania were the first to demand that the examination of the pilots under their supervision be conducted by a competent oculist. The standards, however, were faulty, for the requirement of mere "good vision" was too vague and placed too much responsibility on the personal judgment of the examining oculist. It must be said, however, to the credit of the

1. Houghton, Mifflin and Co., Boston, Mass., publishers.

commissioners, that as soon as their attention was called to the defect, they speedily determined to right it, and asked me to prepare what I considered to be a proper and adequate standard, requesting also that a standard for hearing be added to complete the examination of the special senses.

The following report was accordingly presented to them in February of this year and adopted by them shortly afterward. It is only fair to say that while I personally assumed the responsibility of fixing the standards which are embodied in the report, I took the precaution of submitting them to Dr. Alexander Duane, of New York, and Dr. Charles H. Williams, of Boston, from both of whom I received valuable suggestions. The requirements which follow represent, therefore, in a measure the views of both of these gentlemen as well as my own, and I wish to take this opportunity of publicly acknowledging my indebtedness to them.

VISUAL REQUIREMENTS FOR PILOTS

For apprentices and all candidates for pilots' licenses, normal color-sense is requisite; any imperfection disqualifies.

A candidate must be able to read 6/6 Snellen with each eye separately and without glasses. The eyes must be free from disease and from appreciable muscle error.

All pilots under 50 years of age must submit to reexamination every three years; those over 50 years, every year. More frequent examinations shall be made by order of the Commissioners of Navigation in all cases in which there is a tendency to deterioration in sight or hearing.

If at any of these later tests, vision has deteriorated to such a degree that uncorrected vision does not equal at least 6/9 in one eye and 6/24 in the other, and corrected vision 6/6 in one eye and at least 6/9 in the other, or if there be any imperfection in the color-sense, the license shall be revoked until vision and color-sense have attained the above standard.

REMARKS

All tests shall be made by a competent oculist, acting under appointment of the Commissioners of Navigation. A complete record of each examination shall be kept on file at their office, and a copy shall be given to the person examined if he so desires.

In the event that the official oculist of the board has judged a candidate or pilot unfit for the duties of pilot by reason of defective sight or hearing the candidate or pilot may have the right to submit himself for examination to another oculist not connected with the board, and in the event that the opinion of this oculist differs from that of the official oculist, the board shall request the two oculists just mentioned to select a third who shall be acceptable to the board. A third and final test shall then be made in the presence of representatives of the board, and the decision arrived at, at this test and conference shall be final.

The examiner will observe that the Snellen charts used in the tests shall be exhibited to the candidates at 6 meters exactly, that a good light is thrown on the card and that "care be exercised that each eye is tested separately. During the tests, charts with different lettering shall be employed in such a manner that the candidate cannot become familiar with the letters on the various lines." The color-sense shall be tested with tagged Holmgren's wools and also by a Williams lantern. A selection of confusion colors with the true colors when tested with the green test skein or with the rose test skein of the Holmgren worsteds, or a confusion of red and green with the worsteds or with the lantern, will reject.

DIRECTIONS TO BE OBSERVED IN MAKING THE TESTS FOR COLOR SENSE

1. *Holmgren Colored Worsteds Test.*—Place the whole number of colored worsteds on a table in good clear daylight. Put the green test skein at a distance of about two feet from the other colors and ask the man to be examined to select from the colors all that look to him like this test skein and place them

beside it. Have him understand that he is not expected to find an exact match for the test skein, but that he is to choose all the colors that appear to him of the same general color as the test skein, both those that are lighter and those that are darker in shade. If he does not easily understand what is wanted, let the examiner himself select the colors; then, having returned them to the general heap and mixed them thoroughly, let him call on the person examined to repeat the selection. This demonstration will not enable a man who is defective in his color perception to select the colors correctly, and he may pick out, as looking to him like the test skein, some of the greens and also some of the gray or brown confusion colors.

Note the numbers on the tags of the skeins selected as similar to this green test skein, and also whether the selection is prompt or hesitating.

Return all the colors to the heap, mix them together, then place the rose test skein apart from the rest, and have the person examined select as before all the colors that look to him like it, and note the numbers on the skeins so selected.

No names should be used in connection with this worsteds test, which should be based simply on a comparison of colors.

2. *Williams Lantern Test.*—Turn the rheostat so as to have a medium illumination from the two incandescent lights in the lantern, or, if an electric current is not available, light both lamps, taking care not to turn them up so high as to smoke, then place the lantern 20 feet from the person to be examined about on a level with his head, the side of the lantern carrying the disc with the colored glasses facing directly toward him, and darken the room. Place the shutters so that three lights are shown at one time through either the largest or the medium openings, turn the disc slowly, and have the person examined call aloud the names of the colors as shown, designating them thus, "middle red, right red, left green," etc. Under each color is a distinguishing number which is lighted at the same time as its color, and as the examination proceeds the examiner will note the number of the color shown and the name given to it.

After all the combinations with three colors at a time have been shown, change the shutters so as to show one or two lights at a time and revolve the disc again, noting the results as before.

Calling a green light blue, or *vice versa*, calling a yellow red, or, with the smallest opening failing to see the color of No. 7 (cobalt blue) which transmits less light than some of the others, will not be considered serious mistakes, but the confusion of red and green with each other will reject.

STANDARD FOR HEARING

Words or numbers spoken by the examiner in an ordinary conversational tone of voice must be repeated correctly by the person examined standing with closed eyes 20 feet from the examiner. This degree of aural acuteness must be maintained not only at the initial test for candidates, but also at all subsequent ones.

DIRECTIONS TO BE OBSERVED IN MAKING THE TEST FOR HEARING

Have the room as quiet as possible, place the person to be examined at a distance of 20 feet from the examiner, with one ear toward him. Have the man close his eyes and put his finger over the further ear, then have him repeat aloud the words spoken by the examiner in a conversational tone, and record the distance in feet at which this can be done correctly. Have him turn the other ear toward the examiner and repeat the test.

THE DEPARTMENT OF STATE

The following is an extract from information which has recently, i. e., May 4, 1910, been prepared for the guidance of those surgeons of the Army, Navy, or Public Health and Marine-Hospital Service, who are to conduct, when necessary, physical examinations of candidates for foreign service appointments.

Regarding the matter of vision it may be said that defective vision possible of correction by glasses and not due to ocular disease is not considered as physically disqualifying a candidate for appointment, although in the report of the examina-

tion note should be made of the character of the defect, if any, and of the possibility of and necessity for correction. If correction be found to be necessary, the Department of State will take the matter up with the candidate.

THE NAVY

Candidates for admission into the U. S. Naval Academy are required to have normal visual acuteness, i. e., 20/20 for each eye without the aid of glasses. A normal color sense is also requisite. On graduation a vision of 15/20 in each eye is requisite, capable of correction to 20/20, and freedom from ocular disease. To quote still further from a letter received a few weeks ago from Dr. C. F. Stokes, the Surgeon General of the Navy:

A candidate for the Medical Corps, for civil engineer or for chaplain of the Navy must have 12/20 in each eye, capable of correction to 20/20, and be free from ocular disease.

An applicant for the Pay Corps and the Naval Hospital Corps must have 15/20 in each eye and be free from ocular disease.

For the Navy Nurse Corps (female) there are no specific requirements beyond what is the opinion of the examining surgeons necessary for the proper performance of work.

For appointment as a commissioned officer in the Marine Corps, 18/20 in each eye is required, capable of correction to 20/20.

The requirement for enlisted men in general is 15/20 in each eye. On subsequent enlistment and, in certain instances, on first enlistment, as in the clerical force (yeoman branch), this requirement is sometimes waived, providing there is no disease.

For officers on promotion, the board must certify that the officer is able "to perform efficiently all of his duties at sea."

A moderate error in refraction, if fully corrected by glasses and there is no ocular disease, does not necessarily reject in the upper grades. All candidates are examined for color-blindness before promotion, and defective color-sense is always a sufficient cause for rejection.

Applicants for the position of gun-pointer (already enlisted) must have 20/15 with the right, or aiming eye, and a minimum of 20/20 with the other eye.

These, so far as I am aware, comprise the visual requirements which are in force in the public service of the United States, and with the exception of those projected for the Army and of those already adopted by the Navy, and the Department of State, I think it will be agreed that there is much need of elaboration and standardization. The requirements for pilots, both federal and state, are surely inadequate, and I am convinced myself that were the subject thoroughly investigated the loss in the past of many lives and of much property could be traced to faulty vision in pilots and navigating officers.

Anticipating some action by this Section on this question which is of such vital importance to the country, I have already done what I could to establish better standards, as you have heard. The Surgeon-General of the Marine-Hospital Service is endeavoring to have the Department of Commerce and Labor adopt the standards of which I have told you, and I have written to a prominent oculist in the largest ports of each coast state, enclosing a copy of the Pennsylvania laws and urging the enforcement of similar laws by the commissioners of navigation in his state for the proper control of state pilots.

It will not be an easy matter, however, to influence legislation either in Washington or the various states; nor indeed do the standards whose adoption is urged cover the entire field of our public services. I would suggest, therefore, if it meet with the approval of the Section, that a commission be appointed from its body, to cooperate with the Department of Commerce and

Labor, and with the Marine-Hospital Corps, to establish proper standards and to devise proper tests in making the examinations, for the examination of the eyes of all candidates in their several departments, the duties of whose position demand sharp sight and healthy eyes. And in order that the purposes of this commission may be ratified and supported by the Association at large, I would advise that the representative of this Section in the House of Delegates be empowered to present the matter to that body for its official sanction.

2049 Chestnut Street.

THE ROLE OF PATHOLOGY AND PHYSIOLOGY IN PREVENTIVE MEDICINE*

WALTER L. BIERRING, M.D.

IOWA CITY, IOWA

Preventive medicine, in the nature of things, may well be accepted as the criterion of the state of scientific medicine. That it is again coming into its logical place is due to the great progress which has been made during recent years in all branches of scientific medicine, and in this development the studies in pathology and physiology have been of fundamental nature.

In this symposium I take it that the part assigned to me is to refer in a concise way to the prominent facts contributed through the avenue of pathology and physiology which have influenced preventive medicine. I recognize that this will be largely a review of well-known facts, and I fear there will occasionally be some encroachment on the subjects treated in the other papers of the program.

In the memory of many now living, our conception of the nature of the disease has been revolutionized, and with the recognition that its ultimate processes, whether produced by external agents or the result of modifications in the normal metabolism, are chemico-physical, we have reached a standpoint from which to approach the problem of prevention and cure in a rational way.

TUBERCULOSIS

In no phase of preventive medicine has the knowledge of causative conditions been a greater factor than in the prophylactic control of tuberculosis, the real advance dating from the time when the etiology and infectivity of this disease were established.

It was an interesting fact that the true significance of the pathologic lesions and their infectivity were recognized long before the tubercle bacillus was demonstrated. Klencke in 1843 first demonstrated the infective nature of tubercle by producing general miliary tuberculosis in rabbits by inoculating "tubercle cells." The importance of his discovery was not recognized until in 1865, when Villemin by carefully controlled inoculation experiments on rabbits confirmed Klencke's views and demonstrated beyond doubt the infectiousness of tubercle by transmission from animal to animal.

Klebs in 1868 demonstrated by animal inoculation that the sputum of tuberculous patients contained an infective element which was capable of producing the disease in guinea-pigs. Chauveau in 1868 infected calves by feeding them bovine tuberculous masses. Gerlach in 1870 by ingestion experiments demonstrated

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

the infectivity of milk from tuberculous cows. Tappeiner, in a series of experiments beginning in 1877, demonstrated beyond doubt the infectiousness of phthisical sputum by inhalation experiments. Giboux, in 1882, succeeded in infecting rabbits by confining them in boxes into which tuberculous patients had expectorated, thus demonstrating long before Flügge's classical experiments, the dangers of sprayed particles of sputum of phthisical patients.

Thus the infectiousness of tuberculous matter in man and cattle, the dangers of tuberculous sputum and milk, the identity of the different tuberculous lesions in man and animals, and the established value of animal inoculation as a diagnostic aid were fully known before the birth of bacteriology and before the epoch-making paper of Koch in 1882 announced the discovery of the tubercle bacillus.

Koch confirmed Cohnheim's views as to infectiousness being the best criterion of tuberculous disease, but the establishment of the value of the microscopic search for the tubercle bacillus in diagnosis placed the prophylaxis of tuberculosis on a scientific basis, and demonstrated wherein the sources of danger existed. Subsequently Cornet contributed his exhaustive experiments demonstrating the dangers of dried sputum, indicating one of the principal modes of infection to be by inhalation of dried particles of expectorated material contained in dust from rooms inhabited by tuberculous patients. Later Flügge proved the danger of droplet infection in the immediate neighborhood of such patients.

The entire system of hygienic care of sputum and other discharges has been built up on these results, and in this newer knowledge of tuberculosis the field of general sanitation has been greatly enlarged; the recognition of the widespread prevalence of the infection, the great frequency with which healed lesions were found, and the knowledge of the importance of the character of the tissue soil, led to the adoption of present day sanatorium, open air, and dietetic treatment with all their beneficent results.

Results are at all times most convincing, and in no way is this more clearly shown than in the decreased death-rate from tuberculosis during the past three decades. In England there has been a decrease of 50 per cent. since the discovery of the tubercle bacillus. In New York City during the past twenty years the reduction in the death-rate from pulmonary tuberculosis has been nearly 40 per cent, and in Prussia the death-rate has been notably decreased, being 50 per cent. less in 1903 than 1885. In Boston, during the last thirty-one years the diminution in death-rate from tuberculous disease approximated 55 per cent., a decrease representing in actual saving 14,412 lives. Thus has the sum of human happiness been advanced by this phase of scientific medicine.

TYPHOID—CHOLERA—DYSENTERY

A second interesting chapter in preventive medicine is presented by the studies on typhoid, cholera and dysentery.

Before any successful warfare can be waged against an infectious disease it is of the highest importance to know with precision the nature of the agent which produces the disease, how it invades the individual, what its method of action is, how it is excreted, and finally how it perpetuates itself outside the living body.

The aforementioned diseases are associated principally in their symptoms and pathology with the intestinal tract, and in a search for the causes of these diseases it was but natural that the study should focus itself on the rich bacterial flora of the intestines. While the specific micro-organism for each of them has been determined, it has not been possible to produce the typical clinical picture in the lower animal, so that in a sense there has been a break in the chain of evidence associating a micro-organism with the disease process. Aside from the influence on municipal hygiene and general sanitation, these studies have added to our knowledge in another direction of far-reaching importance—in the discovery of the so-called Pfeiffer phenomenon.

In the early nineties Pfeiffer successfully produced a state of immunity in animals with typhoid bacilli and cholera vibrios in which they could stand, without symptoms, doses which at first would have proved fatal.

In further study he investigated the fate of cholera and typhoid germs introduced into the peritoneal cavity of immunized animals, the germs becoming clumped together and dissolved—the animal remaining in good health. This clumping, agglutination or dissolution, of disease germs under the influence of specific immune agents constitutes the Pfeiffer phenomenon, which in many ways has revolutionized our knowledge of infectious diseases.

A similar agglutination was observed in the serum of a sick human being, also likewise produced in a test-tube, and through the further elaboration by Grueber and Widal was brought forth the so-called Widal test, a diagnostic procedure most valuable in typhoid fever and many other diseases.

The importance of a specific reaction such as the agglutination phenomenon in the diagnosis of fevers with symptoms specially referable to the intestinal tract requiring the isolation of organism from the stool, is apparent.

It is impossible to say how many lives are saved annually and how much disease and suffering are prevented through methods of diagnosis alone made possible by the discovery of Pfeiffer's phenomenon. Indirectly it has influenced the development of protective inoculation, as furthered by Haffkine in cholera, Shiga in dysentery, and Leishman and Chantemesse in typhoid fever.

The rôle of chronic typhoid carriers is now recognized as an important factor in maintaining typhoid infection in a community, and the knowledge that such individuals may exist in any community will strengthen to a very great extent the hands of the health officers in checking the ravages of the disease.

INSECT INFECTIONS

It was also in the study of this class of infections that the transmission of disease by means of insects was specially developed. Much evidence has been brought forward in recent years to show that flies are frequent carriers of typhoid infection, and there can be no question of the proof of the same.

Fisher estimates the duration of life of typhoid bacilli in the bodies of flies as twenty-three days, and finds that they can live for some days on the head and legs of flies, illustrating that there are two ways of transmission—on the surface and within the body of the insect. During the Spanish-American War flies were important agents in the transmission of the disease, and since then a number of epidemics have been traced to this source.

Perhaps one of the most important contributions to modern scientific medicine is the demonstration of the mosquito as an intermediate host in the transmission of malaria and yellow fever. To do justice to this remarkable addition to our knowledge would mean a review of the wonderful accomplishments of preventive medicine in Cuba, South Africa, and other regions once veritable pest regions in the tropics.

To-day the Canal Zone of Panama, for years the grave-yard of the white man, has a death-rate as low as that of any city in the United States.

The problem of life in the tropics for the white man has been solved, since malaria and yellow fever may now be prevented by very simple measures. And these are all results of laboratory studies which have placed in our hands power for good never before wielded by man.

BIOLOGIC AND PHYSIOLOGIC STUDIES

In the diseases diphtheria and tetanus, a new problem is presented. While due to specific micro-organisms, special toxic products are generated, and by learning to cope successfully with these toxins by means of antitoxins, humanity has been greatly benefited. Both diphtheria and tetanus antitoxin sera are active prophylactic agents, while their curative virtues, especially the former, have robbed these diseases of much of their terrors. The use of specific antibacterial serums has thus far not been very promising except in the case of the serum of Flexner and Jobling for cerebrospinal fever, in which it has produced most beneficent results.

The use of bacterial vaccines has no such field of usefulness as the antitoxins just mentioned, either in a curative or prophylactic sense, yet there is reason to entertain a hopeful view as to the future, for the progress within the past ten years inspires the greatest confidence.

The principle of producing a protective immunity by means of vaccines consisting of an attenuated virus, as illustrated by smallpox vaccination, inspired the brilliant achievements of Pasteur, leading to his epoch making contributions in connection with chicken cholera and anthrax, and out of which arose the marvelous researches of Pasteur and his co-workers on the subject of rabies, demonstrating the location of the purest and most concentrated virus in the central nervous system, and gave to the world the wonderful protective inoculation which has reduced the mortality in man to a fraction of one per cent.

The rôle of vaccination for smallpox in preventive medicine hardly requires any emphasis as its efficacy is generally accepted. An epidemic of smallpox is practically impossible in a well vaccinated community. Vaccination is also the only scientific means of controlling smallpox, and its adoption in the place of quarantine, as is the case in Minnesota, is a most logical procedure.

The triumphs of preventive medicine are reflected mainly through the advances in pathology and its handmaid, bacteriology, mainly because it has been more prominently concerned with the disease of distinctly infectious or bacterial origin; but equal benefit has come through the avenue of physiology by a better conception of a large class of noninfectious conditions; for a better knowledge of the functions of organs and their perversions has led to most remarkable results.

Medical science has profited in all its aspects largely from the purely biological researches, and coincident with the progress in the infectious processes a closer study of cell-life has led to the recognition of a vital activity or special function of cells, as illustrated by a better knowl-

edge of the ductless glands. The attitude of Heidenhain in assuming a "vital activity" of epithelial cells resulted in considerable progress in the recognition of processes of secretion and intercellular changes accompanying them. It is an interesting fact that the newer knowledge of the ductless glands is largely the result of cooperation with the clinical domain, and in most instances the newer conception of the function of these glands was contributed by the clinician.

In Hermann's well known work on physiology published in 1883 it is stated in one line that we know nothing of the functions of the thyroid and adrenals, but in the same year the contributions of Kocher of Berne, in an extensive report of the after-effects of complete removal of goitrous glands recognized for the first time the significance of the thyroid in the animal economy. The light which was shed on the vital importance of these glands lit up the entire field of internal secretions which had remained impenetrably obscure for many past centuries.

The intense activity of modern experimental medicine managed to bring to light in less than ten years the following important facts: 1. The relation of the thyroid to natural myxedema and cretinism and the surgical conditions of a similar nature. 2. The effects of the radical removal of a goitrous gland can be obviated by leaving behind a small part of the gland. 3. The extract of the thyroid gland is capable of removing the symptoms due to the natural or artificial absence of the gland. 4. The unrestricted use of thyroid brings on a condition which is very similar to the pathological complex known as exophthalmic goiter or Graves' disease or hyperthyroidism.

Associated with the brilliant chapter of thyroid investigation is that of the relation of the parathyroid to tetany or post-operative spasms. Beebe has observed that the nucleoproteins of the parathyroids are capable of controlling this symptom. MacCallum and Voegtlin discovered that this can be controlled also by the administration of calcium.

Although our knowledge of the function of the suprarenals is far from complete, the relation of the medullary portion to various pathologic and toxicologic states, as chloroform poisoning, shock, nephritis, etc., is recognized. We know it to be an absolutely vital organ, and exerts its physiologic influence by emptying its secretion into the blood; the extract that is obtained has proved of immense practical and scientific importance.

The discovery by Marie of the relation of the hypophysis to acromegaly ranks with the preceding brilliant results.

The production of experimental diabetes by Von Mering and Minkowski by complete removal of the pancreas has established the control of carbohydrate metabolism by the internal secretion of the pancreas. As the knowledge of this function becomes more complete there is hope that the prevention and treatment of diabetes will be on a firmer foundation.

By the studies of these vital organs that three decades ago were thought to be useless, surgery, therapeutics and general medicine have learned many lessons, and the field of preventive medicine has likewise been enlarged.

It is only fitting that emphasis should be given to the recent advances in the physiology of the digestive organs, and their bearing on medicine and surgery, and indirectly on preventive medicine.

The researches of Cannon, Starling, and Pawlow on the movements of the stomach and intestines have greatly

benefited the surgeon and given the internist a better conception of digestive processes and their functional disturbances.

The work in the physiologic chemistry of nitrogen-purin metabolism by Chittenden and Folin has placed modern dietetics on a scientific basis, and this, with the important discoveries relating to the metabolism of the inorganic constituents, such as those relative to acidosis, have opened up a new and hopeful chapter in scientific medicine by suggesting a probable cause and preventive measures for nephritis, arteriosclerosis, diabetes, and other disturbances in nutrition.

CONCLUSION

The purpose and object of preventive medicine is to keep away from mankind those ills which interfere with the pursuit of happiness by crippling physical well-being. More exact knowledge of the cause and nature of disease enables the physician to prevent that damage, and therein lies the rôle of pathology and physiology in preventive medicine.

13½ South Dubuque Street.

THE RÔLE OF THE PHARMACIST IN PREVENTIVE MEDICINE*

JOSEPH P. REMINGTON, Ph.M.
PHILADELPHIA

The words "preventive medicine" have, to a commercial druggist, a significance which he has yet failed to grasp entirely in its far-reaching influences. The term "preventive medicine," according to our lexicographers, means, "something taken, used, or done beforehand to ward off disease." While, in one sense, prophylactics are medicines which are intended to prevent disease, specifically the term "preventive medicine" has a much wider application and means "medicine that aims to ward off disease by properly directed personal and public hygiene."

While the pharmacist has not, and should not have, the proper equipment for diagnosis and the prescribing of remedies in serious cases, he should be imbued thoroughly with the principles of preventive medicine, and, as far as in him lies, bend his energies in the direction of stamping out disease in season and out of season.

It would at first appear that the pharmacist's rôle is necessarily a restricted one and again the public, in some quarters, do not look to the apothecary to advise them not to take medicine, but very frequently such advice, if tendered, is apt to arouse in the minds of a patient or customer a suspicion of ignorance, for the public have been trained to expect that medicines are to be paid for—advice never; and it cannot be denied that a patient coming from a doctor's office, after hearing him discourage the use of any specific medicine for the case, goes right to the drug store and asks the druggist to give him some relief from the hacking cough, because he thinks he cannot afford to travel to some more salubrious climate as his doctor has recommended.

It should always be the aim of the pharmacist to uphold the opinion of the physician, and if the customer demands a medicine which he has been in the habit of using to alleviate his cough it would be the duty of the pharmacist to say a few words against depending on the palliative, and certainly not encourage the patient to use such a weak prop. Just as a physician gives to a patient

the best advice possible, so should the pharmacist refrain from giving any suggestion which would lead to the building of false hopes.

The pharmacist, is, of course, in business; his daily bread depends on his sales and he cannot be expected to give medical advice, for if he does he will be very apt to hear from the physician on the ground that he is trenching on the latter's prerogative, and the conscientious druggist is frequently placed in a very delicate position, for he is at a loss to know to what extent he may go, in discouraging the use of some questionable mixture and just how much he ought to say. Cases are frequent in which physicians have been unwilling to prescribe any medicine whatever, in certain cases and recommend instead, exercise, pure air, pure food, pure water, sleeping in the open air, etc., and when the patient refuses, or finds it impossible from his environment to take this advice, he has bought some preparation from a pharmacist and obtained relief.

A wise and skillful physician would often find it judicious, in order to secure the patient's adherence to preventive measures, to prescribe some safe mixture in addition. Pharmacists have for centuries furnished medicines which are prophylactics—vaccine in all its forms, serums, antiseptics, sanitary appliances and many others, even including drinking water in bottles. The tendency of the modern drug store is in the multiplication of stock and branching out into side lines, many of which are not intended for the exclusive use of the sick.

Pharmacists can do much in the way of preventing infection from noxious germs. Cleanliness has come in with the antiseptics, and asepsis is being vigorously exploited. There have been several practices followed by careless and ignorant druggists which have undoubtedly increased the death rate in the past. Bottles and boxes which have been sent straight from the infected sick room to be refilled, bottles for holding oil emulsions, and other medicines, are usually sent back without cleansing thoroughly.

Corks are particularly dangerous as germ bearers; corks which have been in the mouths of tuberculous patients are often picked up by infants, and as everything goes into the mouth of a baby, is a source of infection. The habit of not removing the old label from the bottle or box coming from the sick room but pasting the new one right over the old dirt is a habit which has been animadverted against for centuries. Unclean, germ-laden hands and fingers in pharmaceutical manipulations should be carefully guarded against, and the disgusting habit, sometimes seen, of using the mouth as a cork phesser, by chewing the cork, is almost obsolete, thanks to continued preaching and teaching. Corks, bottles and boxes from infected sick rooms should be immediately destroyed; in fact, they should never leave the infected room. Prescriptions could easily be refilled by telephoning or having some member of the family, not infected, send a written memorandum giving the number and date of the prescription which is to be refilled, and then have the pharmacist send new containers.

The rejuvenation of corks, particularly for wine bottles and other beverages, is attended with considerable danger and whenever old bottles and boxes come into the store to be refilled they should be disinfected or sterilized, but far better destroyed, so that their power for increasing disease may be eliminated. The intelligent pharmacist, when he is once awakened to the necessity for taking up his daily burden in preventive medicine, will be enabled to do a vast amount of work of benefit to his fellows.

ABSTRACT OF DISCUSSION

ON PAPERS OF DR. BIERRING AND PROFESSOR REMINGTON

DR. W. A. EVANS, Chicago: Discussing the theme of Dr. Bierring, I should like to know whether it is your judgment that health departments should offer their laboratories in the diagnosis of venereal diseases? Are the procedures conclusive enough and at the same time simple enough to be within our field?

Discussing Professor Remington's subject, has not the time come to standardize the sale of antitoxin? Antitoxin for curative purposes should not be given promiscuously any more than flour or quinin. On the other hand, it should not be sold for \$1.50 a thousand. The way to standardize its sale is, first, to abolish "returns." This will require machinery for quick moving of the product. Second, to reduce the advertising and introduction expense. Third, to make its sale a cash transaction. Fourth, to have but two sizes—1,000 units and 5,000 units. Such a system should reduce the price to 30 to 40 cents a thousand, retail. Antitoxin at this price would save lives through (a) prompt use, (b) larger dosage.

DR. LESTON H. MONTGOMERY, Chicago: Pharmacists, while dispensing our prescriptions, are careless sometimes about removing the collection of dust and other detritus about the corks and necks of their bottles. I have noticed this. Take simple syrup, for instance; there may be deposits from flies and other filth which has accumulated. On more than one occasion I have gone behind a prescription counter and courteously and quietly called the attention of the druggist to such conditions. If a bottle prescription is filled, detritus, debris, dust, germs of disease, etc., may thus be dispensed. You will notice this as you examine and shake the medicine in the bottle at your next visit to your patient. Particularly is this true in collyria. In fact this condition of sediment is often present in other prescriptions that are dispensed. Of course not all registered pharmacists are careless in this respect, some are sanitary and scrupulously clean and remove whatever collection or deposit there may be about the cork or mouth of a bottle before they dispense a prescription.

I am careful about permitting a druggist to refill my prescriptions, unless he has my consent. I have printed on my blanks these words, "This prescription must not be refilled without my order," or the words, "Non repetatur" printed thereon, unless it is something that is very ordinary and doesn't do any harm.

To illustrate, I have a patient, a lady, who has a mitral lesion, who is taking my prescription. She has a friend who has heart disease. My patient, desiring to favor her friend, gave the number of the prescription on the label of her bottle and she had the prescription dispensed and nearly died as the result of taking that medicine. She evidently had a different condition altogether from that of my patient.

DR. GEORGE EDWARD FELL, Buffalo, N. Y.: There is more to this subject than most of us appreciate. Some of my prescriptions have been filled for seven years after they were made. I heard of it by my patients telling me that they had been giving that prescription around, since it was made, which was seven years before. If such things do occur why not have the pharmacists help a little and disinfect the bottles that come back, if they are going to allow them to come back? I don't believe it is within our power to prevent the druggist from refilling prescriptions, or the patients from taking them back, even if we do lay down our law and request them not to do it. If it could be done, it would be a great help. I believe the pharmacists can do a great deal to aid us in preventive medicine in many ways.

DR. SENECA EGBERT, Philadelphia: In regard to the paper on pathology and physiology, I think we should all appreciate the wonderful assistance that has been given preventive medicine by these two sciences which, as the gentleman said, were thought thirty or forty years ago to be of no practical benefit to the doctor. Some of us have been advocating the exploitation of the knowledge that we now have. There is no question that we need to do that to get popular education; but we have only opened the door, as it were, in the matter of original research; and while I do not believe

that the ordinary medical school is the place for carrying on all of the original research work, I do believe that every one of us ought to support those who are capable of doing it and who are doing it as admirably as our colleagues in the profession have done in the past two or three decades.

With regard to the paper of Professor Remington, there is another line in which the druggist, it seems to me, can be of tremendous assistance to us, and that is in his counter-prescribing in venereal diseases. If the druggist will not do that, and if he will send the patient to the doctor, there is some chance not only of prophylaxis but of education, a chance that otherwise might be missed. I do believe that this is one phase of the pharmacist's work wherein a great deal of good can be done, by telling a man or a boy who comes to him for a cure for diseases of that kind: "No, I am not the man for you. We pharmacists, as well as the doctor, realize that to-day those diseases are no longer to be looked on as harmless troubles; they are diseases dangerous to you and to the community as well, and I cannot prescribe for or treat you."

DR. WALTER L. BIERRING, Iowa City, Iowa: I appreciate that in the field of preventive medicine we are making use, in a coordinate way, of the knowledge of the different fundamental principles which apply to the entire subject. There is also much in the suggestion of having laboratories associated with boards of health or with other bodies interested in preventive medicine, in order that special research work may add greatly to our knowledge along this line, and at the same time benefit the cause of general sanitation.

In Iowa we have been conscious for some time of the fact that there is much discrimination and hardship imposed by the high price of antitoxin, so the department of health has taken on itself to introduce a method of furnishing antitoxin, not free, but at a reasonable price. It has made arrangements with several manufacturers of antitoxin so that it is able to furnish the same at a rate of about 40 cents per thousand units; a supply is kept on hand at different depots throughout the state to facilitate its being easily obtained and arrangements are also made to have it transferred readily from one city to another as the particular depot may run short in its supply. In that way it is kept constantly fresh, and kept moving, which was a point specially mentioned in this discussion. By this method there can be no thought of pauperizing the citizen, yet it brings the antitoxin to such a low figure that no one will have an excuse for not receiving its benefit; and again, where the people are indigent and unable to procure it the county or municipal authorities will furnish it as needed.

I am sure what was said by Professor Remington in reference to the opportunity for infection in a modern drug store is very applicable, and therein lies a duty for physicians to do away with the pernicious practice of having prescriptions refilled, thus making such a medium as the drug store a source for the spread of infectious diseases.

PROF. JOSEPH P. REMINGTON, Philadelphia: The American Pharmaceutical Association has taken up the matter of what is called the declaration of the prescription; and the mooted question of the ownership, which has been discussed for so many years, is likely to be taken up in a business-like way. It is the intention to refill prescriptions when indicated by the physician, and only on his approval. You will see, later on, I have no doubt, published in THE JOURNAL of the American Medical Association, just what action was taken recently at the meeting at Richmond, Va.

I believe that if this Section, or the American Medical Association, would get up a properly worded request or circular which could be sent to the druggists throughout the United States, calling their attention to causes of infection in dispensing prescriptions, it would be received in a proper spirit. It is very desirable to call the attention of the druggist and the physician to this subject, so that causes of infection may be reduced to a minimum. Let the physician go in and say, if any bottle, box or container comes from an infected home destroy it at once and have the prescription refilled with new and clean containers. It only needs a little education on the part of physicians and pharmacists to remedy the evil to a very great extent.

AUTO-INTOXICATION AND ALLIED INTESTINAL TROUBLES

AS A POSSIBLE CAUSE OF CERTAIN VASCULAR AND FUNCTIONAL DISTURBANCES OF THE EYE *

HIRAM WOODS, M.D.
BALTIMORE

This paper is the result of a personal conversation in October last, the participants being our Chairman and Secretary and myself. We met in Philadelphia, at the invitation of the Chairman, to discuss the program for this meeting.

Among other matters, ocular disturbances from various toxic influences were considered. The papers which have already appeared were reviewed, and especially the pioneer work of de Schweinitz with his chemical helpers, Edsall and Fife. These researches, it will be recalled, had to do with inflammatory lesions, especially those of the uveal tract. We thought of lid, conjunctival and various functional anomalies of the ciliary structure, things of daily observation, which resist local treatment, are prone to relapse, and which are not uncommonly associated with those remote symptoms which de Schweinitz has aptly defined as "conjunctural." That is, one finds associated with certain lesions of the lid structures or functional derangement of the anterior uvea—just the history and symptoms which, if associated with uveitis, would lead one to think that the internist (having at command chemical means to investigate defects of metabolism) could throw light on etiology. Is there more in this than association? If so, how far has the physiologic chemist enabled us to go?

This question was put to Dr. Edsall, and he was invited to follow an interrogatory paper with one explaining what we want to know. His reply was that he felt that, after his contributions, accessible to all, there was nothing more definite to add. We felt that it was useless to seek farther. Still, our own clinical observations led us to think the matter worth presentation, and this position has been, since October, confirmed by a paper by Dr. J. F. Shoemaker¹ of St. Louis. The lesions of the adnexa which I wish to consider are those of the lids and mucosa. De Schweinitz describes the former in his text-book under the title, "Hyperemia of the Lid-Border (Hyperemia Marginalis, Vasomotor Blepharitis)." He says:

The margins of the lids have an unpleasant, slightly swollen, red appearance. Exposure to cold, wind or any strain on the accommodation causes a feeling of heat followed by burning and lachrimation. The redness is caused by the passive congestion of the superficial blood-vessels. Scales or crusts are absent, or but sparingly present.

Discussing the etiology of blepharitis, without specially mentioning the vasomotor variety, but evidently with it in mind, he says that it may follow in the wake of an exanthem, may result from ametropia, "inflammations of the tear-sac, stricture of the nasal duct, and obstructive disease of the posterior nares, although it may be difficult to decide whether the blepharitis has caused the closure of the lacrimal passages or whether this has developed the blepharitis." Dr. Shoemaker, presenting the clinical conjunctival picture, with a possible autotoxic cause in view, says:

As a rule, the cases I have observed have very little or no secretion. The eyes feel uncomfortable, particularly with their use in artificial light, and the blood-vessels of the bulbar conjunctiva are considerably engorged. The diagnosis must be made, however, from the history of indigestion or constipation, together with other symptoms of autointoxication. Some of these symptoms are drowsiness, especially after eating, dizziness, periodic attacks of headache, certain diseases of the skin, particularly of the erythematous or urticarial types, various nervous disturbances and aching and stiffness of the muscles which might be confused with, or attributed to muscular rheumatism. The patients may not complain of any of these symptoms, but inquiry will usually develop the fact that they suffer with one or more of them.

Before attempting to couple the lid and conjunctival disturbances and discussing the possibility, in certain cases, of an autotoxic cause, I want to add a third class. I allude to recurrent circumcorneal injection, recurrent asthenia of the ciliary muscle, spasm of accommodation, and the condition known as hysterical accommodation spasm, or cyclospasm. It is well described in Posey and Spiller's book, "The Eye and Nervous System." It has been studied specially by Parinaud, and his description is given:

The spasm may be partial or total, unilateral or bilateral. It is similar to that produced by eserine, and has as its chief characteristic a displacement toward each other of the punctum proximum and the punctum remotum—that is to say, there is a diminution of accommodation at both ends of the line.

Here, then, are three vascular or functional troubles which we see constantly in routine practice. To connect them with remote causation demands first, painstaking exclusion of known causes. For instance, in hyperemia of the lids, lacrimal obstruction, as de Schweinitz observes, is frequent. As he says, again, it is not always easy to say which stands as cause, infection to the lids from the excretory apparatus, or to the latter from the lids. I am sure that often the course is toward the lids, and that at least one factor can be readily overlooked. Definite accumulation of mucus in the sac or persistent epiphora are easy enough; but lesser grades of obstruction are not so readily diagnosed. Ziegler told us about this years ago, and devised probes of great value. I am sure that infection, or, possibly, irritation, from the nose can often do no more than cause catarrhal swelling of the mucosa in the canaliculus or even shutting of the puncta. Chronic hyperemia of the lids often disappears after dilatation of the puncta and canaliculus without going into the duct at all. Nitrate of silver solutions of 2 to 5 per cent., applied to a swollen turbinal, and a somewhat persistent use of such a mildly stimulating agent as an oil solution of menthol in the nostrils, often cure chronically congested lids. Injection of the conjunctiva, as described by Shoemaker, stands in close relation to lid hyperemia. The structures are but parts of one vascular area.

Circumcorneal injection, in the absence of corneal lesions, of course, focuses attention on the anterior part of the uveal tract. This brings us to the most important of the recognized causes of lid and conjunctival hyperemia and functional disturbances of the ciliary muscle, namely, refraction and muscular errors, and the varied relations they have to each other. It is not my purpose to do more than mention this causative factor. In such an association, for instance, as hyperopia and exophoria, one could naturally look for relapsing ciliary cramp; but every clinician knows that cases occur in which his best efforts, along line of recognized causes, fail to cure.

* Read in the Section on Ophthalmology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Shoemaker, J. F.: Etiology and Treatment of Certain Forms of Conjunctivitis, *Am. Jour. Ophth.*, January, 1910.

If at first relieved, the patients relapse. Why do they not stay cured?

A second essential, if relapsing eye troubles are to be attributed to remote disturbances, is the more or less constant association of ocular lesions or derangement of eye function, with symptoms of the supposed causative disease. This association, I take it, is what de Schweinitz means by the presence of certain things which lead one to "conjecture" a toxic cause. If one of the three classes of eye trouble occurs when the patient is constipated, when he has periods of neuralgia, when he is suffering from what he calls "nervous dyspepsia"; if local remedies do not relieve, or, at the most, give only temporary relief; if all these symptoms, including those of the eye, clear up when the remote trouble is removed, then we are justified in suspecting causative relation. If these simultaneous eye and remote troubles occur not once, but repeatedly, and if they occur not in one, but in many patients, this suspicion becomes a conviction. I do not consider it necessary to prolong my paper with narration of cases; brief allusion to one will suffice.

A man of 25, total refraction error D 1. of hyperopia, with less than D 0.5 astigmatism with the rule. Vision immediately after cycloplegia distant vision (d. v.) 20/15; near-point accommodation 12 cm.; orthophoria, d. v., exophoria 3° at near.

Gradually, from this state of things, he develops a reduction of d. v. to about one-half, with recession of his near point to 30 cm. With or without correction of his low error, this thing occurs. Why? Invariably, in three or four such experiences, he has given a history of pain after eating and constipation; there has been foul breath, and he has learned that this association exists. He leads a sedentary life, and makes his living by keeping books. Homatropin restores normal eye function, and so long as he keeps his diet regulated, and constipation does not overtake him, ciliary cramp does not return.

This case is narrated because I have linked ciliary disturbances with those of the lid and its mucosa. Dr. Shoemaker has covered these sufficiently.

While we can eliminate recognized causes, and prove clinical association, we cannot as yet fulfill a third condition—explanation of pathogenesis. We call it auto-intoxication; and there are good reasons for so doing. For instance, we see conjunctival hyperemia and "vasomotor" blepharitis in diseases of known infectious origin; note their occurrence in the beginning, through the course and after the exanthemata. We see all grades of ciliary involvement, from asthenia of transient type to complete and stubborn paralysis, after various infectious diseases, typhoid fever, chicken-pox, scarlatina and diphtheria. These lesions we attribute to toxins, and it is to be specially noted that since the advent of diphtheria antitoxin we see fewer cases of postdiphtheritic paralysis.

Secondly, in diseases not themselves infectious, but capable of forming toxins, we note similar eye troubles. Nephritis, diabetes and occasionally pregnancy serve as examples.

Thirdly, there is good reason for thinking of the intestines as the source of this autotoxic influence. After the proved association between uveitis and intestinal disorders, the work of de Schweinitz and Fife seemed to afford chemical proof of a pretty satisfactory nature. Cases of pupillary derangement, clearing up after expulsion of intestinal parasites, are recorded. Bruns of New Orleans recited such a case in discussing my paper² on ocular neurasthenia at our meeting in 1907. There is the peculiar edema of the conjunctiva

in trichinosis. In two cases I saw during the past winter, the edema involved the bulbar conjunctiva, between the limbus and external canthus, presented a peculiar yellowish reflex, and was totally inexplicable, till fever, blood examinations, etc., cleared the diagnosis. In the first volume of Osler's "Modern Medicine" this eye symptom of trichinosis is recorded.

The reason, then, for calling these eye disturbances, associated with various intestinal disorders, "autotoxic" is that they bear a strong similarity to eye troubles of either known general infectious nature, or to those seen in systemic diseases capable of producing toxins. Shoemaker attributes the conjunctival congestion to the fact that the conjunctival "substantia propria consists of adenoid connective tissue which is richly supplied with blood-vessels and lymphatics, the walls of which are irritated, and become diseased by these poisons." He quotes Deland as authority. Such effects on blood-vessels, with subsequent exudates and hemorrhages, are well-recognized results of toxemia. So, too, are varying degrees of interference with muscular function, from slight impairment to complete paralysis. In the presence of changes, characteristic of toxemia, it is but natural to think of the latter as a cause, in spite of the fact that we do not know the toxin at work or are even sure that there is any such influence. Autotoxic diagnosis is a matter of inference, though undoubtedly the most probable, in our present state of knowledge. This is as far as we can go till the physiologist and chemist blaze the way. So far they have not given us very dependable diagnostic means or explained pathogenesis much beyond the hypothetical stage, at least so far as my limited knowledge goes. A recent publication shows their own uncertainty. Among the Oxford medical publications of last year is a most interesting and instructive book by Arthur F. Hertz, entitled "Constipation and Allied Intestinal Disorders." Speaking of auto-intoxication or copremia, Hertz says:

There is no entirely satisfactory method of estimating the activity of bacterial decomposition in the intestines. Jaffé thought it could be measured by the amount of indican, and Baumann by the amount of ethereal sulphates in the urine. The results obtained, however, give no definite indication as to the degree of autointoxication, which may be present, as different putrefactive bacteria produce different products, some of which are comparatively innocuous, whilst others are excessively poisonous. Hence an increase of the quantity of indican or ethereal sulphates in the urine is no evidence that excessive production of other more poisonous products is occurring, and on the other hand, it would be quite possible for severe intestinal auto-intoxication to occur in the complete absence of any change in the urine which could be demonstrated by Jaffé's or Baumann's methods. Both indican and ethereal sulphates have been found to be increased in some cases of constipation, but by no means constantly . . . and Strauss and Philippson found a diminution in the ethereal sulphates as often as an increase. When excess of these substances is present in the urine of constipated individuals, it may just as well be due to the increase in the quantity absorbed, owing to the longer stay of the feces in the colon, as to an increase in the quantity produced. . . . There is thus at present no chemical evidence that an abnormal amount of decomposition occurs in the intestines of constipated people. . . . It is, however, possible that even in the absence of any increase in the production of poisons, the slow passage of feces through the intestines might lead to autointoxication by giving more time for the absorption of products of bacterial decomposition. But definite evidence is still wanting to show that the products of ordinary bacterial decomposition in the intestines can give rise to poisonous symptoms on absorption.

Hertz then discusses the poisonous effects of ethereal sulphates, sulphuretted hydrogen, "which is normally

present in traces in the colon," ammonia, the amido-acids, indol, and concludes that all are only slightly toxic. Regarding the latter, he thinks that the amount apt to be absorbed in constipation would not affect a healthy individual, but that those "with an abnormal nervous system" would react. He sets aside ptomaines as the cause of toxic symptoms in constipation because none has been found in the urine or feces of persons suffering in this way. He says:

Volatile fatty acids and most of the products of bacterial decomposition of carbohydrates are rapidly oxidized in the body so that they are not likely to produce any poisonous effects. . . . It is, of course, possible that the symptoms are due to the absorption of some unknown poisons. But no accurate means have yet been devised for investigating this possibility. . . . Though there is no evidence that such a condition as copremia exists, yet many of the results of constipation are more easily explained by the theory of auto-intoxication than in any other way. This is particularly the case with some of the nervous symptoms. . . . This auto-intoxication is probably due to the abnormally long period during which the feces are present in the intestines, and to the consequent excessive absorption of poisons, and not to any increase in bacterial decomposition.

Relative susceptibility is then discussed. The liver is "the chief defense against auto-intoxication," and its power to convert toxic into harmless substances is presented. Even after absorption, no great harm is done if the eliminative organs are in good shape.

Lastly, Dr. Hertz states that the ultimate effect of toxic absorption depends on the state of the organ itself. He emphasizes the harmful effects of constipation in producing functional diseases and on "a depressed nervous system."

I have introduced these views of Dr. Hertz because they seem to me full of significance. Reduced to their simplest terms, they indicate that "auto-intoxication" from constipation and other intestinal disorders is but a working hypothesis, and seems to explain, better than any other, clinical findings. They also throw great doubt on the value of usual methods of chemical investigation. There are certain interesting clinical facts which I have observed, having some bearing on this contention. Exactly the same ocular symptoms which I have detailed have been observed in chronic appendicitis. Two of the patients suffered from repeated attacks of appendiceal pain before operation, and functional eye symptoms came immediately after their subsidence. One girl developed in different attacks "cyclospasm," a manifest astigmatism which disappeared after cycloplegia, and finally a chorioidal exudate. There were no symptoms of "auto-intoxication" and no constipation. The interesting point is that the patient had an inflamed adherent appendix removed four years ago, and has had no functional eye disturbance since. I alluded to this case in my paper on ocular neurasthenia in 1907. Of course, it is possible that the pain produced neurasthenia, and that the so-called "hysterical accommodation" resulted from this. Still, the girl is a remarkably level-headed person, and not in the least hysterical, in the ordinary acceptance of the word. The other patient was an educated woman in the thirties, who presented repeated and inexplicable lengthening of the punctum proximum. I knew nothing about her appendix symptoms till she came to tell me about a prospective operation. This was two years ago. I have seen her frequently, as she has come at my request, and I have never found relapse of the functional eye trouble. The only abdominal symptoms in both cases were those of appendicitis. I cannot connect auto-intoxication with

these, and incline to the belief that there is some other path to eye irritation.

Again, in cases in which there has been association of eye anomalies with constipation and its toxic results, I have had the urine carefully studied. In some of them the chemical findings were negative; however, treatment directed to the intestines is keeping the patients well. Allusion has been made in this paper to unrecognized infection as a cause of the symptoms under consideration. I have now under care a woman, 63 years of age, who has had for twelve years peripheral lens striations of the non-progressive type. She preserves normal central vision. She is gouty, a free liver—or, rather, has been—and came to me this time for obstinate conjunctival congestion of the right lower lid. She brought with her a diagnosis of constipation, indicanuria, auto-intoxication, etc. There were no manifest symptoms of lacrimal trouble at first, and for several weeks we worked along autotoxic lines without improvement. Then she developed a not very annoying epiphoria, and a probe introduced into the duct showed no stricture. The canaliculus was not split. But from this time, under the one probing and repeated washing of the sac, there has been steady lessening of the chronic conjunctival hyperemia. By contrast the case shows the essential difficulties of diagnosis.

In conclusion, I think that there is enough association between the eye disturbances named and manifest symptoms of auto-intoxication from constipation to justify the belief of causative relation. There is reason to think that the same eye troubles can follow intestinal lesions which do not essentially produce toxic products. It seems that the physiologic chemist is not yet in position to help us much in proving the diagnosis, and that until he is we must study these obstinate cases from a clinical standpoint only. If we are ever to explain them or to relieve them, we must view the eye as the receiving as well as the sending end of what we call remote disturbances.

842 Park Avenue.

ABSTRACT OF DISCUSSION

DR. J. F. SHOEMAKER, St. Louis: The three forms of ocular trouble mentioned in Dr. Woods' paper are frequently observed. Each has more than one etiologic factor, and I believe that intestinal toxemia will be recognized as the underlying cause in an ever-increasing number of cases. I am unable to furnish any chemical proof in the way of evidence that definite poisonous substances are to be found and isolated in patients suffering thus; but, I believe that carefully collected clinical evidence is of great importance and that there are such substances. I have observed more cases of the second class, viz., those of patients suffering with conjunctival hyperemia and inflammation, than of the other two classes. In more than one case of conjunctivitis, after I had exhausted my best efforts in the way of local treatment with little or no benefit, great relief was soon obtained by treatment of an existing constipation or indigestion. In such cases a hearty dinner will often undo more in a single night than can be accomplished in weeks in the way of curing by local treatment, particularly if much meat and alcoholic stimulants are taken. Some of these patients often are more uncomfortable at night than during the day. Several patients have complained of awaking during the night with quite severe pain in the eyes, and most of them have more or less discomfort when they first awake in the morning and state that they have some difficulty in opening their eyes, not on account of the presence of any pus which glues the lids together, but on the contrary, on account of the lids being so dry that they adhere to the globes.

While I have, of course, had cases of the third class, in which the ciliary body is affected, with circumcorneal injection,

spasm of the ciliary muscles of subnormal accommodation, I have not been able to satisfy myself that they were caused by auto-intoxication, although I have more than once suspected it. I have at present, however, a patient who is a confirmed dyspeptic and suffers with constipation, and who, whenever she uses her eyes for near work for a short time, complains of a sharp pain in her left eye as though she had a foreign body in the eye. The most careful and painstaking correction of her refraction and muscular imbalance does not relieve the trouble. I am convinced that the cause of the irritation is some toxic substance absorbed from the intestinal canal.

One of the most chronic and persistent cases of conjunctivitis I have ever had was in a young woman who had a chronic appendicitis. She was troubled with constipation, so that I do not know that the appendicitis had anything to do with causing the conjunctivitis, but as we are told that constipation is sometimes caused reflexly by a chronic appendicitis, this latter condition may be the primary cause of some of these troubles. R. T. Morris reports a case of double central chorioiditis occurring in a man who had a chronically inflamed appendix. With the removal of the appendix the inflammation of the chorioid stopped short and cleared up with practically normal vision. Some patients may present symptoms of auto-intoxication and yet deny that they have any indigestion or constipation. I believe that the explanation in some of these cases is that while the bowels move every day, perhaps, yet the evacuation is not complete and enough fecal matter is retained in the large intestine to produce a toxemia. In one of my cases there existed a spastic condition of the sigmoid which prevented the complete evacuation of the bowel, and at times caused quite stubborn constipation. It was not until a rectal examination was made by a competent internist that the true condition was found and treatment was satisfactory. In such cases ordinary laxatives or purgatives are of little value in treating the constipation.

I am of the opinion that in the great majority of cases the trouble arises because meats or protein foods are not properly digested, thus permitting excessive putrefaction to occur in the intestines. Some people seem able to digest properly only a small quantity of meat, while others may not be able to digest any well. As Thayer and Turek have pointed out, in such conditions a few grams of meat may be enough to produce severe symptoms from the poisons formed, and while the amount of poison may be very small it may, nevertheless, be quite injurious because of its being constantly repeated.

DR. JUDSON DALAND, Philadelphia: To demonstrate absolutely the relationship between intestinal toxemia and functional or organic ocular diseases would necessitate the isolation and experimental administration of these toxic substances and the reproduction of these lesions. The character of the toxic substance or substances, unfortunately, is not known, and therefore we are compelled to fall back on general clinical evidence, which is strong enough to produce a belief in a causal relationship, in certain cases, between, for instance, the condition known as biliousness and certain ocular disturbances.

To-day intestinal toxemia may be viewed from two standpoints; one, concerned with aberrations or variations in metabolism, and a second concerned with putrefactive changes in the contents of the colon—a statement which shows the vast field of possibilities. The diagnosis of intestinal toxemia or of disturbed metabolism is often not difficult. The simplest and most common form of intestinal toxemia is that symptom-complex known as biliousness. Occasionally there exists what may be termed fecal retention; the bowels move daily, but the colon is never empty. A simple method exists by which this condition, so frequently in association with intestinal toxemia, may be determined, namely, by irrigating the colon after the morning evacuation of the bowels; if more than a half teacupful of feces is recovered, fecal retention is present. Feces thus obtained should be examined microscopically and chemically.

The chemical sign of intestinal toxemia of putrefactive origin that has attracted the most attention is the presence in the urine of indican or the indoxyl sulphate of potassium. It is now believed that this substance in itself is non-toxic,

but plays the rôle of an indicator, indicating that substances formed during the process of putrefaction have been absorbed. These substances are exceedingly variable in number, combination and quantity, depending on the character and amount of foodstuffs ingested, and variations in digestion. Certain of these substances may be detected by a skilled organic chemist after prolonged labor; while others are unknown or unrecognizable. It is well known that intestinal toxemia may exist in the absence of indicanuria or skatoluria.

DR. J. L. THOMPSON, Indianapolis: I have many patients coming to me who tell me that they have been to their physicians and that the latter have been treating them with electricity and similar methods, and I look into the eye and see no edema, no hemorrhages and no trouble with the optic nerve; I have written to the patients' physicians to give half a large tumblerful of a saline purgative every day, every two days or twice a week, and then have them come to see me again. I do not have them stop the electricity. The patients come back in three weeks greatly changed. When one is in doubt the bowels should be cleaned out thoroughly.

DR. L. CONNOR, Detroit: I remember the custom of the late C. R. Agnew, many years since, when I was studying ophthalmology under him, of telling patients suffering from one or more disturbances of the eye which were related to abdominal infections that they should so modify their living habits as to restore an equilibrium in their metabolism. For this he prescribed systematic walking, with such clothing as made it easy; appropriate attention to food, the alvine evacuation, the care of the skin; and I observed that the patients recovered from their ocular disturbances. The same practice is continued to the present. Dr. Woods told me recently that his patients with corneal trouble did better if they lived in the open air. In short, many ophthalmologists have recognized these conditions though unable to trace to their exact causation, in spite of the successful empirical treatment. As a stimulus to farther study Dr. Woods' paper has done us good service. We may hope for better results as every doctor gains a minimum of real ophthalmic practice by his working knowledge of infectious diseases of the eye and its simple refractive defects. The observations of 135,000 physicians added to those of the 3,000 ophthalmologists ought to furnish material for conclusions nearer the facts of the relations of both gross and fine lesions of the eyes to defective abdominal metabolism.

DR. A. G. BENNETT, Buffalo, N. Y.: In my experience as oculist to the Children's Hospital, Buffalo, I get numberless cases of inflammations of the conjunctiva and cornea that improve almost immediately as attention is directed to the intestinal tract. This is the type of case that I was taught to treat with syrup of the iodid of iron and yellow oxid of mercury ointment. My experience has been that when you look after the intestinal tract you do not need very much local treatment.

DR. R. D. GIBSON, Youngstown, O.: This paper brings out the necessity of the oculist's having had a general medical experience before going into the eye specialty. The man who has not undertaken to practice medicine before he goes into eye-work does not appreciate the effect of intoxications on the eye. We find that children with phlyctenular conjunctivitis are children with bad digestive troubles, that have been given sweets to eat, that have fermentation. Many years ago I learned that calomel given in small doses, frequently repeated, was almost a specific for this trouble. It was the eliminative effect of the calomel on the alimentary canal. There is much virtue in the admonition of the old Scotchman, "Fear God and keep your bowels open."

DR. S. L. ZEIGLER, Philadelphia: This question of auto-toxemia and the perverted metabolism from which it arises brings us face to face with the great problem of the pathology of the future, which will undoubtedly turn our attention from the study of bacteriology to the study of physiologic chemistry. It seems to me that chemotaxis is the pathogenic process that originates many of the diseases we are studying, and possibly many of those that we have been ascribing to bacterial invasion. Some years ago I wrote a paper on the relation between errors of diet, errors of metabolism, intes-

tinal errors, and the causation of corneal ulcers. There is no question but that the ingestion of sweets, tea, coffee, and other articles of that character, will create a disturbance that is first manifested in the intestines or in the stomach, from there is transmitted to the nose and thence through the tear-duct to the eye. That is rather a circuitous route for the transmission of this vicious influence, but that is the course it takes. Eales of Birmingham has long since called attention to intra-ocular hemorrhage due to constipation, and I believe we should carefully consider the important rôle that constipation bears to these disturbances. I reported some years ago a case of this character in which the constipation sometimes lasted for ten days. It originated in a severe attack of dysentery. There were recurrent ciliary hemorrhages, and following these a cataract, which was afterward operated on successfully. In the other eye there were hemorrhages that became organized and remained there.

As the remedy for these conditions we should first cleanse the bowels, thus relieving the constipation and removing a great deal of this deleterious material from the system. We also have the nose to clear out, thus improving the breathing process, and thereby increasing the oxidation of the system. We likewise have the skin to look after, and very often much can be accomplished by sweats, whether by means of vapor baths, electric light baths, or pilocarpin. These are all problems that we must consider, and it seems to me desirable that Dr. Woods should continue this investigation and bring it to a consummation. In order to do this successfully he will undoubtedly require the cooperation of the physiologic chemist. This will be extremely difficult to accomplish for two reasons; first, it is almost impossible to procure these biologic products in large enough quantities for analysis, and second, the skilled physiologic chemist is still a *rara avis*.

DR. HIRAM WOODS, Baltimore: In a case just seen, a man 38 years old, had lost one eye some years ago by accident. He had been in the hands of half a dozen people trying to get relief from asthenopia. He said that at times, without warning, his vision would become obscure. He unloaded a whole lot of glasses; among them one was a plus 1 cylinder, 150 degrees, and another, a plus cylinder at 80 degrees. All had been given by capable men, simply because when he went to these men he had this manifest refraction. Under prolonged scopolamin cycloplegia the only error was $1\frac{1}{2}$ spherical. With that he had cl. v. 20/15, and accommodation from 8 out to 20 inches for Jaeger 1. I told him to come the next time he had an attack. When he came, the first thing I did was to put a drop of atropin in the other eye. He had an anterior synechia there and I wanted to see if that was the source of irritation. That did not help him. The second time, vision had fallen from 20/15 to 20/50; his accommodation range was 11 to 15 inches. He was constipated, had a foul breath odor, and was very irritable. That man was given calomel with a saline purge and allowed to go on with his work. He came back after two days with a 20/15 cl. v. and accommodation restored. I have got him in the hands of an internist who has put him on a restricted meat diet, intestinal antisepsis. I believe this is an example of many cases we will find if we look for them and study this question of metabolism.

DEVELOPMENT OF THE TEMPORAL BONE*

G. W. BOOT, M.D.
EVANSTON, ILL.

I wish to describe briefly some of the points of difference between the os temporale of the infant and that of the adult.

In the os temporale of the nine-months fetus¹ the ossification of the three centers is well advanced, so that they are all attached to each other, but neither firmly nor throughout the whole of their adjoining edges. The

squama temporalis is thin and light. In its posterior portion is seen the series of perforations which mark the outer wall of the antrum tympanicum (which is often incorrectly called the antrum mastoideum but which distinctly is not a part of the processus mastoideus). The processus zygomaticus is light. The fossa mandibularis is merely a shallow depression below the posterior extremity of the processus zygomaticus. The middle and posterior roots of the processus zygomaticus are distinct, but the anterior root has not yet appeared.

The annulus tympanicus is a mere ring. The bony meatus acusticus externus does not yet exist. The annulus tympanicus is attached at this stage by both anterior and posterior extremities, though but slightly. The anterior and posterior tubercles are indicated, but are so small that unless their later development were known they would not be worthy of being named. The greater part of the annulus tympanicus is not yet attached to the os temporale.

Part of the pars petrosa is well developed. The processus mastoideus is wholly absent. There is no processus styloideus. The fossa jugularis is very shallow. The sulcus sigmoideus is discernible, but is shallow and not well marked. The part of the bone that fills in the space under the canalis semicircularis superioris has not yet appeared. The petrotympanic fissure, the canaliculus chordæ tympani, the tuba auditiva and the semi-

Fig. 1.—Temporal bone of a 9-months-old fetus, cut to show the location of the antrum tympanicum. Note that the antrum lies wholly above the level of the zygoma.

canalis tensoris tympani are not yet separated from each other, but all form one common cleft between the annulus tympanicus and the pars petrosa.

DEVELOPMENT OF THE ANNULUS TYMPANICUS

In the os temporale of the 9-months fetus (Fig. 1) the annulus tympanicus is a mere ring just wide enough to contain the groove for the attachment of the membrana tympani. It is attached at its two extremities to the squama temporalis alone. There is no attachment to the pars petrosa.

In the temporal bone at about the time of birth (Fig. 2) the annulus tympanicus has become fused with the pars petrosa, which partly overlaps the lower posterior part of the annulus. The attachment has taken place, not through any growth of the annulus, but through a growth of the pars petrosa outward to meet the annulus. The tuberculum tympanicum anticum and the tuberculum tympanicum posticum are distinctly marked, but are not prominent.

In the 3-months-old child there is a distinct growth of bone from the annulus toward the common opening of the tuba auditiva, fissura petrotympanica and semicanalis tensoris tympani.

In the 6-months-old child the annulus has widened considerably at the lowest point and also at the two

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

¹ Throughout this article, reckoning of the age of the fetus is by lunar months.

tubercles, so that its opening is no longer circular, as it was at birth, but is elongated in the vertical diameter.

At a year old and at 1 year and 3 months old the widening has progressed, but is still most marked in the lower part of the region of the posterior tubercle, so that there is now a marked projection of this tubercle into the opening of the annulus.

At a year and 6 months of age the growth of the annulus is not only toward the opening of the annulus, but also horizontally outward at the posterior part of the annulus, so that this part has a rough outer margin similar to that presented in the adult bone for the attachment of the cartilage.

From this age on the anterior and posterior tubercles gradually approach each other, until, at 3 years, they have met and fused together, still leaving an opening which represents the original opening at the annulus tympanicus. While this opening usually closes, it does not always do so, and one not infrequently sees adult bones with this defect present.

Fig. 2.—Temporal bone of the infant at birth, somewhat inclined, showing the first rudiments of the mastoid, the perforated outer wall of the antrum, and canalis facialis opening on the outer wall of the bone about the middle of the annulus tympanicus. Note that the petrotympanic suture lies between the antrum and the developing mastoid.

In the temporal bone of the new-born infant the free margin of the annulus is smooth, but from the age of 1½ years the outer margin becomes thickened and roughened.

In proportion, as the annulus widens and closes, the fossa mandibularis deepens from the shallow marking seen in the new-born infant to the deep cavity seen in the adult bone.

DEVELOPMENT OF THE PARS MASTOIDEA

There is no pars mastoidea in the fetal bone and very little in the child up to the age of 1 year. The first marked indication we have of a mastoid appears at the age of 1 year and 3 months. It is true that, before this time, there has been some change in the shape of the portion which is subsequently to become the pars mastoidea. It has extended outward as the posterior attachment of the annulus has widened.

In a child of 1 year and 3 months there is a distinct bulging outward at about the level of the upper posterior extremity of the annulus. This bulging continues until, at 2 years, the projecting pars mastoidea has reached

down to the level of the inferior surface of the pars petrosa.

LOCATION OF THE SUTURES IN THE OS TEMPORALE

In the nine-months fetus there is but one suture, the petrosquamous, in addition to the attachments of the annulus tympanicus to the squamotemporalis, which latter are known as the tympanosquamous anterior and tympanosquamous posterior.

In a child at birth there is, in addition, the petrotympanic suture anterior and the petrotympanic suture posterior, which are directly continuous with the tympanosquamous anterior and tympanosquamous posterior respectively.

By the growth of the pars petrosa the bony tuba auditiva and the semicanalis tensoris tympani have become shut off from the canaliculus chordæ tympani and are wholly surrounded by the pars petrosa. The canaliculus chordæ tympani lies between the tympanic plate and the pars petrosa. The petrotympanic fissure is what remains of the anterior squamotympanic suture. A portion of the pars petrosa becomes wedged in between the tympanic plate and the pars squamosa, dividing the squamotympanic suture into two portions, which become the squamotympanic anterior and the petrotympanic

Fig. 3.—Temporal bone of a child of 2 years cut to show the location of the antrum. Note that the antrum lies wholly below the level of the zygoma.

anterior. The squamotympanic posterior eventually becomes obliterated and the petrotympanic posterior is shown only by a narrow line which still contains a canal for the transmission of vessels.

In the course of time all the sutures become obliterated more or less, but that portion of the petrotympanic suture lying behind the antrum tympanicum may be traced in the adult bone by the denser part of the pars mastoidea corresponding to its location. The cells lying in front of it are comparatively small, while those lying behind it are apt to be large. This suture thus forms the dividing line between the antrum tympanicum and the larger mastoid cells. The obstruction to the mastoid cells by this suture explains why mastoiditis beginning in the antrum tympanicum is so often much more destructive near the tip of the mastoid than near the antrum.

The squamopetrous suture along the superior surface of the bone is quite a wide cleft in the new-born child. It leads into the tympanum and antrum through the tegmen and, as is well known, by its failure to close leaves those dehiscences which predispose to meningeal and brain infections.

LOCATION OF THE CANALIS FACIALIS IN THE YOUNG BONE

The course and shape of the canalis facialis do not vary so much in themselves as in their relation to the surrounding parts, and this is chiefly dependent on the development of the pars mastoidea.

In the new-born child and for several months afterward, that is, until the mastoid begins to develop, the opening of the canalis facialis is on the outer surface of the pars petrosa of the os temporale. It lies just outside and behind the opening in which the processus styloideus is afterward formed. It is about opposite the middle of the annulus tympanicus and 2 mm. posterior to that ring. Its location is such that, if the ordinary incision for the complete mastoid operation were made, the nerve would be in great danger of division. This location explains why facial paralysis of the baby is caused by instrumental delivery. With the development of the pars mastoidea at the age of 1 year and 3 months it begins to recede from the outer surface of the os temporale and to be covered by the overhanging processus mastoideus until in the adult bone it lies fully 1.5 cm. within the plane of the outer surface of the processus mastoideus.

LOCATION OF THE ANTRUM TYMPANICUM IN INFANCY
AND ITS MIGRATION IN LATER LIFE

In the temporal bone of the new-born child the recessus epitympanicus is much smaller comparatively than it is in the adult. Instead of extending across the whole width of the tympanum it occupies a little less than half that space and extends directly upward from the middle of the tympanum.

The antrum tympanicum lies directly above the recessus epitympanicus and extends obliquely upward and backward from it. Thus the antrum tympanicum drains into the top of the tympanum instead of into its upper posterior part, as in the adult. In the 9-months fetus (Fig. 1.) the antrum extends from 2 mm. in front of a vertical line through the posterior limb of the annulus to 2 mm. posterior to that line. It is wholly above the level of the processus zygomaticus. In the child of 2 years (Fig. 3) it has come to lie wholly below the level of the processus zygomaticus and has assumed the adult position with reference to the surrounding parts. This migration is well advanced at the age of 1 year and 3 months.

800 Davis Street.

ABSTRACT OF DISCUSSION

DR. GEORGE E. SHAMBAUGH, Chicago: Instead of beginning at the bottom and working up, it is the rule to-day for the men entering special fields to begin at the top, and comparatively few ever do work down and acquire that knowledge of the fundamentals of the special field which should constitute their preparation for the clinical study of cases. Too often the thing the prospective specialist aims to do is to see and treat cases, and as a rule it is the operations, the most difficult part of treatment, that he wants to undertake first. Too few of the men who begin in this way ever do master the fundamentals of their specialty, the detailed knowledge of anatomy, the embryology, the physiology of their subjects, which is the sort of training that makes it possible for them to become expert clinicians. The internist does not begin by attempting to treat diseases of the liver, nor the surgeon by operating on the liver. They first become grounded in embryology, the anatomy and the physiology of the organ, and then they are in a position to study intelligently disease and to apply treatment. The specialist in otology or ophthalmology ought to begin in the same way to acquire first of all a knowl-

edge of the fundamentals of his subject. The dentist, who is working in a highly specialized field of medicine, is much more careful to get adequate training in the fundamentals of his specialty, although the clinical problems he has to meet are in no way so difficult to deal with as in our specialty. It is only here and there that a specialist undertakes, as Dr. Boot has done, to work up the fundamental anatomy of the temporal bone. This is something that cannot be acquired from text-books nor from drawings; it can be learned only by the handling of the preparations themselves.

ADAPTABILITY OF SCIENTIFIC INFANT-
FEEDING TO GENERAL PRACTICE*

H. LOWENBURG, A.M., M.D.,

Instructor in Diseases of Children, Jefferson Medical College;
Pediatrist to the Lebanon Hospital, Philadelphia, and to
the Jewish Maternity Hospital; Pediatrist to the
Jewish Seaside Home, Ventnor, N. J.

PHILADELPHIA

Realizing that human milk is the best food for babies, the pediatrist determined to his own satisfaction long ago that, this failing, the best substitute is properly adapted cow's milk. To state that the percentage, fractional or American system of infant-feeding is a panacea for the nutritional ills of infants during the first year of life would be to adopt a fallacy and create a position readily made untenable. To regard this as the best and easiest means of adapting cow's milk to the digestive capacity of the individual is rational and scientific. It affords the best way of carrying the greatest number of feeding cases, both sick and well, to a successful issue. That it is not too intricate and complex for adoption by the general practitioner can be proved by demonstrating that failure results, not from the method, but from causes independent of it. For convenience these causes of failure may be grouped under three headings.

I. CAUSES OF FAILURE DEPENDENT ON THE PHYSICIAN

For many of these causes of failure the pediatrist himself is to blame. In his teachings and in his writings he has made the subject too complex. Didactically he has taught not enough principles and too many methods, and in the hospital wards he practices none of them, leaving the matter of feeding to the inexperienced intern, confining his own efforts to his private patients and the consultation room. The result has been that nearly all hospitals for children are carrying many semimarantic infants who neither gain nor lose, and who are finally taken home or die from some intercurrent affection. From this the general practitioner takes his cue that perhaps the matter of percentage feeding is too intricate and too complex for the pediatrist himself. This is not the case. It simply emphasizes a fault, almost unpreventable, that even in the best-conducted institutions the number of infants to each nurse is too great. The result is that the patients suffer from the lack of that intimate contact and perfect hygiene which is desirable and necessary to the successful conduct of any medical case, and, further, that the pediatrist is unable to give the time and study to each individual patient.

In this connection I believe the subject of sufficient importance to recommend that each large hospital and college should have on its staff a pediatric dietitian.

* Read before the North Branch of the Philadelphia County Medical Society, and by invitation before the Southeast Branch of the same society.

The multiplicity of algebraic monstrosities proposed and taught as methods of milk modification, "simple and practical," have justly bewildered the practitioner and he eagerly takes refuge behind the directions plainly printed on the label of some patented food. The laboratory modification of milk, while theoretically ideal, is most often impractical and too expensive and will not be considered here.

For home modification the practitioner, as well as the pediatricist, should become familiar with one, and by no means more than two, methods of milk modification. These can readily be acquired with a little patience and they soon become a part of his therapeutic equipment. I would recommend Holt's top-milk method for the majority of cases in private practice, and Baner's cream-and-milk method for institutions and the poorer class of private work and dispensary patients as there is no waste. The more these methods are used the clearer and more simple they become.

The physician should know the normal constituents of human and of bovine milk, and the physical as well as the chemical and bacteriologic differences. Without giving these their full value, failure will be absolute. It is insufficient to diagnose indigestion; he must designate the variety of indigestion, whether it be the protein, fat or sugar which is at fault, and act accordingly. He must seek to adapt the milk to the baby, not the baby to the milk, remembering that each baby is a law unto itself. He must pay no attention to the child's age with the idea of determining its digestive capacity or the amount to be fed or the interval of feeding. It must ever be borne in mind that cow's milk was never intended by Nature for babies. Chapin's researches in comparative physiology and biology have abundantly proved this. Therefore, the nicety of his percentage adjustment will fail unless the physician notes the physical differences between the curd of bovine and that of human milk. In this connection, as will be emphasized later in more detail, he must apply to his percentage formula the advantages to be derived from sodium citrate, cereal decoctions, whey and pancreatization¹ (peptonization). Milk must be clean. Accurate percentages will not prevent infection from a dirty milk.

Many practitioners, as well as pediatricists, have a mistaken idea as to just what percentage feeding means. I have no patience with that teaching which claims that it is a matter of importance as to whether the amount of any one of the different constituents varies a quarter or a half of 1 per cent. one way or the other. Such fine adjustment is not only unimportant, but impossible. The completed preparation, I venture to say, rarely if ever would analyze to correspond to the written formula. Nor is this necessary. Any attempt to secure this would lead to disaster and confusion and justly bring the system into disrepute. What percentage feeding means and affords is a simple and scientific way of thinking and of adapting the milk to the infant's digestive capacity. The first formula is always an experiment, and by percentage feeding any one or more of the various constituents can be diminished or increased. It cannot transform cow's milk into human milk, but with it the physician can attack rationally and scientifically that element which is responsible for

the indigestion, feeling that subtle satisfaction which one experiences when doing a thing for a reason.

Though I cannot give detailed reasons, I would advise against too frequent weighing, too frequent inspection of the stools, too frequent changing of the formula, to which the two former lead, and against attaching too much importance to the presence of a few curds and some mucus and the occasional occurrence of a green stool.

The physician cannot afford to be lazy. The results and the rewards are just as great as any in medicine. He who can transform a shriveled, discolored, weakened mite into a pink, fat, laughing babe has accomplished as brilliant a thing as surgery ever did. This percentage feeding, if properly interpreted and properly applied will do more frequently than any haphazard system of feeding or patented infant food. The physician must not scorn to teach the mother the importance of details or to soil his hands by going into the kitchen and showing her how to make up the first formula and the various milk diluents. He will have an apt pupil who will eagerly follow in the lead of his enthusiasm.

II. CAUSES OF FAILURE DEPENDENT ON THE MOTHER AND ENVIRONMENT

Other things being equal, the most important thing on which a successful issue depends is the intelligent cooperation of the mother—with emphasis on "intelligent." Hysteria and meddlesome interference have no place in the therapeutics of pediatrics. The mother must choose between her medical adviser and her well-meaning but poorly informed relatives and friends and her own notions as to what is right or wrong. She must promise not to interfere, to carry out orders to the letter, to believe that black is white, or to dispense with her physician and to assume the responsibility herself. This cannot be too strongly urged on the mother of a prospective patient. To my mind maternal control is the most important preliminary. Attention to details, quantities to be fed, intervals of feeding, the time consumed in taking the milk, position of the infant while feeding, picking the baby up after feeding, cleanliness of the nipples and bottles, are all matters which make or mar a successful outcome and the blame must not be placed on the system of feeding, whatever that may be.

Environment is a potent factor for good or for evil. Proper clothing, proper cleanliness of the mouth, proper ventilation and sufficient out-door airing are essentials that cannot be neglected. Too much coddling and playing with the infant ought to be avoided. Infants should be expected neither to be amusing nor amused. A little wholesome neglect is very often the best tonic to a poor digestion. Percentage feeding cannot hope to cope with ignorance and squalor met in the home of the slum dweller any more than can aseptic surgery. The practical demonstration of a valuable and proved theory is here impossible. I have encountered many instances, however, in this class of patients in which, with patience on the part of the physician, the cooperation of the mother was obtained and with surprisingly brilliant results. Kerley has had a similar experience amongst a large number of dispensary patients and tenement dwellers in New York City.²

III. CAUSES OF FAILURE DEPENDENT ON THE INFANT

There are some infants who cannot digest cow's milk in any form. It is true that these cases of idiosyncrasy

1. The term "pancreatization" is used advisedly, as students and some practitioners associate the term "peptonize" with pepsin. A peptogenic milk powder contains 15 grains of sodium bicarbonate and 5 grains of extract of pancreatin. The terms pancreatize and pancreatization, therefore, explain this.

2. Kerley, C. G.: Tr. Sect. Dis. Children, American Medical Association, 1906.

are rare, and yet they do occur, and unless recognized lead to disaster. Other patients there are who possess an intolerance for fat. Whenever persistent vomiting occurs three common etiologic factors should be seriously considered, viz.; faulty hygiene, fat or sugar indigestion and congenital hypertrophic pyloric stenosis. Any one of these, alone or in combination, must be proved or eliminated. The character of the vomitus, together with the time of occurrence, associated with other symptoms, will usually admit of a correct conclusion and suggest the remedy. In these cases an easily performed and too much neglected procedure is stomach-washing.

Premature infants, congenitally weak ones, rachitic and marantic patients, all present feeding problems different from those of the ordinarily healthy bottle-fed baby and require peculiar and delicate manipulation to start them on the road to recovery. This can best be secured through careful percentage feeding, rationally applied. In this connection it must be emphasized that properly to prescribe a formula for an infant not only includes the giving of correct percentages for the case in hand, but also the ability to overcome the difficulties of digestion peculiar to the individual and the other causes of failure which have been described. It may not be amiss to discuss here the more important details of procedure when ordering the first formula, and the methods employed in meeting the feeding problems encountered in the more difficult cases.

IV. DETAILS OF FEEDING

In an endeavor to determine the infant's digestive capacity the history of every child should be carefully investigated with reference to its weight at birth, its present weight, the causes for discontinuing breast-feeding, the various foods and milk combinations which have been tried, its appetite, quantities fed and the interval of feeding, the presence or absence of vomiting, constipation, diarrhea, the color, odor, frequency and consistency of the stools together with the persistent presence or absence of curds, fat, mucus, pus or blood. The patient's physical state should be noted with special reference to nutritional changes indicating marasmus, rickets or scurvy. Trouble is rarely encountered when transferring a healthy breast-fed infant to the bottle.

In weaning these infants it is best to determine the strength of the mother's milk by analysis and then to endeavor to supply a mixture, slightly weaker, especially in protein and fat, than this analysis would indicate. Sudden weaning must be avoided wherever possible. One bottle should replace a breast-feeding for two or three days and the effect noted on the stomach and bowels; then two bottles are given, and so on until the entire breast-feeding is replaced. The various percentages are now increased in the same gradual manner until at a year, or thereabout, the infant is receiving plain cow's milk. The entire process of weaning should occupy from four to six weeks. Frequently the results at weaning are quite as good where an analysis of the maternal milk cannot be previously made. Here a formula representing percentages of protein, fat and sugar somewhat weaker than those of average breast-milk (P. 2 per cent., F. 4 per cent. and L. 7 per cent.) may usually be employed with success as the first formula.

In prescribing the correct percentage of fat no two cases can be treated alike. It is therefore difficult to arrange any general rule. Vomiting an hour to an

hour and a half after feeding is a prominent symptom of fat indigestion, especially when the vomitus is sour, smelling like rancid butter. Associated with this, as a rule, are frequent green, greasy movements, usually acid in reaction and containing lumps of undigested fat. Less often the stools may be constipated, greasy, white and foul. Thus having, in a rough way, determined the infant's fat capacity, the percentage is decided on. It is best to commence with 1 per cent. to 1.5 per cent. and gradually to increase the amount as tolerance is established. The quantity should never exceed 4 per cent. and in the majority of instances it is wise not to go beyond 3.5 per cent. Some infants cannot digest fat at all. This class of patients is becoming decidedly more numerous as our diagnostic ability increases. These babies must be fed on modified skim-milk from which all the fat has been removed, or on fresh butter-milk containing cooked wheat flour and sugar. In other cases fat intolerance can be overcome without reducing the percentage of fat by properly pancreatizing the formula. This is a valuable and too little-employed maneuver. It must not be continued too long or the very purpose for which it was used will be defeated. My own experience with it would place it among the life-saving measures to be depended on especially in extremely asthenic cases of marasmus. It must also not be forgotten that rickets and scurvy may follow the feeding, over a prolonged period of time, of percentages of fat which are too low.

With reference to the digestibility of the protein elements, particularly the paracasein (curd³), authoritative opinion is somewhat at variance. It was formerly taught that this, or rather the indigestibility of the curd of cow's milk, constituted the crux of the whole question of artificial feeding. Many present day authorities deny this, some, notably M. Budin of France, going so far as to feed undiluted cow's milk, with reported good results.⁴

Whichever may be right, the fact remains that curd indigestion is an existent and troublesome condition. Its prevention or correction becomes, therefore, a matter of extreme importance. A healthy new-born infant should not receive more than 0.5 per cent. to 0.75 per cent. of combined proteins. If this is tolerated the amount is slowly increased until at six months from 1.5 per cent. to 2 per cent. is given, and at the age of from ten months to one year 4 per cent. can as a rule be digested. While frequently cases are met in which stronger percentages are digested with ease and benefit at an early age, the rate of progression just detailed does not hold in the case of very weak infants in cases in which distinct curd intolerance exists, notwithstanding the age. When curded, green, slimy stools, associated with colic and irritability, or hard, dry, white movements, which readily crumble, indicate curd indigestion the initial treatment should be a purgative dose of castor oil followed by whey feeding for a few days. Whey contains about 1 per cent. soluble protein and is easily digested. Then small amounts of paracasein are added and the effect noted as these are increased. In exceptional cases it may be necessary to pancreatize the formula for a short time. By this means larger

3. The terms "paracasein" and "curd" are used as synonyms in keeping with the most advanced chemistry of the protein of milk. The coagulable protein is held in suspension by its combination with calcium phosphate and is called calcium casein (formerly caseinogen). This is changed by rennet into calcium paracasein, from which the paracasein is separated as an insoluble curd by small quantities of dilute hydrochloric acid. The earlier term for the curd was casein.

4. Cotton, A. C.: *Diseases of Infancy and Childhood*, p. 129.

amounts of paracasein can be taken, the danger of rickets being thereby minimized. The time of pancreatization is gradually reduced and the pancreatization omitted as soon as possible. After this the addition of some efficient digestive ferment to each bottle or to every other bottle just before feeding is an excellent aid until the digestive function has been completely established.

In many instances the curd is rendered readily digestible by the use of one or two grains of sodium citrate for every ounce of milk and cream in the mixture, as first advocated by Wright and Poynton of England, and later by Van Derslice of Chicago. The early teaching of Jacobi,⁵ advocating the use of cereal decoctions as a curd attenuant, still holds good as an excellent means of rendering the paracasein easily digestible, and has received recent emphasis from the work of Chapin, who employs dextrinized gruels. The cereal decoctions provide a certain amount of starch, which, according to the investigations of Kerley,⁶ can be digested and assimilated by infants as young as nineteen days. Ordinarily, barley-water made from the grain is to be preferred, either full strength or diluted one-half with boiled water. If constipation be present, oatmeal-water used in a similar manner makes an excellent substitute. My own experience with the old-fashioned flour-ball, baked to a bread-brown, grated and added to the amount of a half a dram to each bottle just before feeding has been eminently satisfactory in facilitating protein digestion. Occasionally whey may be employed as a diluent of milk, cream or top-milk, as the case might be, in order to render the curd finer and more susceptible to the digestive juices. In these cases the whey must be heated to 150 F. to destroy the action of the ferment. Beyond this point, 158 F. to 167 F., the lactalbumin will become coagulated.

Sugar is rarely a cause of trouble. The new-born infant should receive from 4 per cent. to 5 per cent. and the amount rapidly increased to 7 per cent. This is continued up to nine months, when it is gradually reduced to 4 per cent. at the age of one year. Frequent, watery, acid stools that excoriate the buttocks, associated with a sour, watery vomitus, flatulency and colic, are indicative of sugar indigestion. Besides marked wasting, a deficiency of sugar produces a subnormal temperature. Infants who are receiving too much sugar and who do not suffer from indigestion are fat, flabby and anemic and are frequent victims of scurvy and rickets. Theoretically, milk-sugar should be employed, but practically plain ordinary cane-sugar answers as well and is cheaper, cleaner and more accessible.

Any formula, however accurate in composition and however scientific in its adjustment to the infant's digestive peculiarities, must always be regarded as an artificial food. As such it must be reinforced by those elements which will cause it to approximate Nature's product in freshness, cleanliness and antiscorbutic and antirachitic qualities. The finished product should therefore be made from certified milk, should be well iced and should never be kept longer than twenty-four hours. Fifteen grains of sodium chlorid should be added to each twenty ounces of formula, and expressed beef-blood, freshly made, or orange-juice in half-dram or dram doses should be given between bottles on an empty stomach.

CONCLUSION

Thus it has been shown that failures with this system of feeding depend on causes foreign to it, and that success can be attained only by studying the needs of the individual and meeting them scientifically. The strongest argument in favor of accurate feeding is that results, both immediate and remote, far excel those obtained by any other method. It is a matter of daily occurrence for the specialist to see infants with a history somewhat as follows:

Born in normal labor. Weight at birth, 7½ pounds to 9 pounds. Age, six months. Present weight 6 pounds and some ounces. Breast-fed for one week. Discontinued the breast because the doctor or the nurse considered the milk insufficient to nourish the baby properly. Placed on indifferently modified cow's milk. Continued to vomit and cry. Colicky, irritable and restless. Stools green and contain curds and mucus, or white and dry. Discontinued milk. Put on barley water, then whey and cream. Vomiting; bowels continued bad. Put on pancreatized milk. Agreed for a while. Started to vomit again. Child fed irregularly with indefinite amounts. Loss of weight continuous. Then ran the gamut of condensed milk, malted milk, and various prepared foods, and four or five able physicians, until this bit of starving, crying, vomiting, purging humanity is thrown into the lap of the pediatricist and his reputation put to the test to work a miracle!

And can he do it? Yes, in the majority of cases with the child free from tuberculosis and syphilis. How does he do it? By studying the needs of his patient and meeting them by carefully adapted cow's milk. The physician can do as well, and by doing less he does not do justice to himself or accomplish his full duty by his patient. He has learned more difficult things than percentage feeding, and the time is not yet when he is ready to acknowledge his inability to do so and leave these cases to the specialist.

CHILDBIRTH AFTER APPARENT MENOPAUSE

L. BUCKLE, M.D.
NEW YORK

C. H., a well preserved and healthy looking woman, aged 50 years, always menstruated regularly and never had any genital troubles till 15 years ago. At that time she gave birth to twins, making the number of children seven in all. About a year later menstruation returned but with considerable irregularity; and in another year it ceased altogether. Two years ago, 11 years after the cessation of menstruation, she began to feel out of sorts; she lost her appetite, had nausea and felt weak. She was examined and treated by several physicians, including myself, at various times, but her true condition was not diagnosed and she remained unrelieved. One doctor told her that she had a growth and an operation would be necessary to remove it. The others treated her for gastritis, nervous dyspepsia, etc. She began to worry over her troubles and became much emaciated, anemic and nervous.

One day she came into me and said, "Doctor, I have a cancer and I feel it move around here," pointing to her abdomen. But this time ballottement, fetal heart-sounds, milk pressed out from nipples, and other signs pointed to an undoubted pregnancy. She must have been then in the sixth month, for about 3½ months later, I delivered her of a boy of normal size and weight. About a year after this birth, menstruation returned and since appears regularly every month.

Pregnancy eleven years after cessation of menstruation is rather rare. So also is the return of normal menstruation after a cessation of thirteen years. These unusual features seem to justify reporting the case.

VEIN-TO-VEIN TRANSFUSION OF BLOOD *

GEORGE MORRIS DORRANCE, M.D., AND NATE GINSBERG, M.D.
PHILADELPHIA

In a previous paper, dealing with the transfusion of blood in the human species, we presented a summary of the literature on this subject and a description of both the old and modern methods of performing transfusion. At the present time, the method in vogue in the performance of this operation is the direct junction of the vessels either by suture or some mechanical appliance. We intend to discuss only certain features pertaining to the operation and we offer this preliminary report, which is based on the development of a new technic, under three heads: (1) the advantages of the vein-to-vein method of performing transfusion over the arteriovenous method; (2) the indications for employing transfusion; (3) the contraindications to transfusion.

I. ADVANTAGES

The artery-to-vein method has been advocated in the last few years by investigators of the subject, notably by Crile. Anastomosis of the vessels is established either by means of a modification of Payr's original tube, or by direct suture of the vessels. Tubings of various types are also advocated, especially by Brewer.

At the best, the operation is a delicate one and should be performed with a full realization of the risk, both to the recipient and to the donor. To the recipient, the dangers incident to the transfusion are the transmission of disease, hemolysis and acute dilation of the heart. The first of these is readily eliminated by a careful inquiry for a history of syphilis or other transmissible disease, supplemented by a rigid physical examination. With regard to hemolysis, the conditions necessary for its occurrence are as yet imperfectly known, and the clinical tests proposed for their detection have not proved of much practical value. We have not, thus far in our experience, had a case of hemolysis. In the case reported by Pepper and Nesbit, obscure changes were undoubtedly present before transfusion was done.

Acute dilatation of the heart from overengorgement is a grave accident which cannot always be avoided when the arteriovenous method is employed, even by the exercise of all possible care on the part of the surgeon. As will be shown later, however, this accident is practically impossible with the vein-to-vein method of transfusion, because the principal factors in its production, namely, increased pressure and volume of the blood-stream, are eliminated.

The advantages claimed for the employment of the arteriovenous method of transfusion are: (1) that sufficient blood-pressure is obtained to introduce the blood quickly from the donor into the circulation of recipient, and (2) that the blood obtained is richer in oxygen content. On the other hand, the method suffers from various disadvantages.

1. The operation itself is beset with many technical difficulties and should not be attempted by any one who has not perfected his skill by repeated experiments on animals.

2. The size of the vessels can never be determined beforehand. Frequently, the radial artery is found to be so small that some other artery must be exposed for

use. The impression of the size of the peripheral arteries which one gains in the dissecting-room is erroneous, since, in the living subject, they are of considerably narrower lumen than those observed in the cadaver.

3. The pressure and volume of the blood-stream, when the arteriovenous method is employed, are sometimes so great as to cause acute dilatation of the right heart, which is a grave complication, appearing rapidly and frequently proving fatal. It undoubtedly explains some of the sudden deaths that occur during transfusion. In Crile's animal experiments, acute dilatation was often noted, and Cole and Winthrop mention it in their work. We have observed it twice in our human cases, and for this reason, the vein-to-vein method suggested itself to us.

The technical difficulties, encountered in the arteriovenous method, of performing transfusion have led to the development of various instruments, principally modifications of the original Payr's tube. Under the most favorable conditions, even in the hands of an experienced operator attempts at transfusion will often fail, but failure in these cases is due to insuperable obstacles, such as abnormally small, or sclerotic arteries, or deep-seated vessels buried in a thick layer of adipose tissue.

In vein-to-vein transfusion, on the other hand, the surgeon is dealing with the superficial vessels, which are easy of access. Moreover, a gradual flow is obtained so that danger of engorgement and the resulting sudden dilatation of the right heart are avoided. The size of the structures and the ease of access make it a simpler procedure than the arteriovenous method. The principal advantage we suggest for the vein-to-vein method of performing transfusion, is its simplicity. There is no danger to be considered except the possible one of hemolysis.

II. INDICATIONS

The basis for classification of the diseases or acute emergencies necessitating the performance of transfusion has been previously stated at some length. In general, transfusion is employed either to save life or to hasten the patient's recovery. After severe hemorrhage, we have two conditions to fulfil; first, to make up for the loss of fluid in the patient's blood-vessels, and second, to increase the number of oxygen-carriers, (red corpuscles). The first of these conditions can be fulfilled by the injection of saline solution, either subcutaneously or intravenously. The second can be fulfilled only by the transfusion of human blood.

The indications for performing transfusion are therefore as follows: the sudden depletion of the vascular system due to grave accidents, or following operations, as in the case of severe tonsillar hemorrhage, and in hemorrhage occurring during the course of typhoid fever; hemophilia; melena; poisoning with carbon dioxid, coal-tar derivatives and other substances characterized by the production of methemoglobin; and pellagra, in which the transfusion of blood from a patient, who has recovered from the disease, has been found beneficial in a number of reported cases.

III. CONTRAINDICATIONS

It is of no value in severe infections, in the cachexia of cancer and in tuberculosis. In pernicious anemia and in leukemia, transfusion has disappointed the great expectations which the introduction of the method aroused for the cure of these hopeless conditions. Transfusion is decidedly harmful in cases of purpura hemorrhagica, and whenever hemolysis is taking place.

* From the Laboratories of Experimental Surgery in the University of Pennsylvania.

* Read before the College of Physicians of Philadelphia, May 4, 1910

The above claims are based on experiments performed on dogs. The transfusion of blood was obtained by employing veins; as jugular to jugular or better, jugular to femoral, in this way eliminating any possible negative pressure or suction. No difficulty was encountered in successfully transfusing enough blood to resuscitate a dog that was practically exsanguinated. This experiment could be repeated again and again on the same dog by clamping the donor's vessel and bleeding the recipient until practically pulseless; the clamp was then removed and the blood allowed to enter the recipient's circulation until the pulse and respiration returned to normal, while symptoms of hemorrhage developed in the donor. Communication between the veins was established by means of Sweet's modification of Payr's tubes.

In concluding, we wish to express our appreciation of the services rendered by Messrs. Burleigh, Hayward, Pitt and McElhone, undergraduates in the University of Pennsylvania.

NOTE.—After this paper had been put in type, we performed a vein-to-vein transfusion on a woman for a very severe hemorrhage following a ruptured extrauterine pregnancy. The pulse before was very weak and rapid, about 160 per minute. Five minutes after the medial cephalic of the husband was connected to the median cephalic of the wife, the pulse was much fuller and 140 per minute. After the blood had flowed thirty minutes the pulse was good, full and 120 per minute. No abnormal heart sounds could be heard.

THE CAMPAIGN AGAINST DIPHTHERIA AND SCARLET FEVER IN CHICAGO *

I. D. RAWLINGS, M.S., M.D.

Assistant Chief Medical Inspector, Chicago Department of Health
CHICAGO

These two diseases are constantly endemic in Chicago, each day bringing its quota of reports to the health department. In diphtheria and scarlet fever, perhaps to greater extent than in any of the other more serious endemic diseases which are prone to become epidemic, large cities, as a rule, demand an adequately manned contagious disease bureau and expect great vigilance and diligence of those in charge in their efforts at preventing epidemics.

Chicago until recently was woefully deficient in her safeguards against epidemics of these two diseases. In spite of repeated warnings she chose to ignore the recommendations for adequate protection and was content with the following conditions as regards diphtheria and scarlet fever.

For several years prior to 1907 the function of the health department in these two diseases had been little more than advisory to the attending physician, who practically had delegated to him the protection of the public against the spread of contagion. The physician made the diagnosis, gave the family such instructions as he chose regarding quarantine, reported the case if he chose to comply with the city ordinance, and, if he reported it, used his own pleasure about having the premises placarded, and the time of ending the case.

Because the activities and energies of the few medical inspectors were needed in fighting smallpox or in other equally urgent duties, such as antitoxin administration and intubation, the contagious disease bureau was forced to admit its inability to compel the reporting of diphtheria and scarlet fever cases, and therefore extended to the attending physician, as the price of reporting the case and cooperating with the department, the privilege

of "assuming responsibility" for the prevention of the spread of contagion. By simply writing the magic word "assume" in a certain space on the reporting postal card the physician enabled his patient to escape practically all surveillance of the bureau of contagious diseases, and no warning placard was posted.

This plan of allowing the attending physician to "assume responsibility" may have resulted in an increased number of cases being reported at its inception, but in 1904, when I first became intimately acquainted with its results, I was speedily convinced that it was unpractical and not justified by existing conditions, when all other large cities of the United States, and even the majority of progressive villages in the vicinity of Chicago, were requiring the reporting of cases by physicians and the posting of warning placards.

Under this plan of "assuming responsibility" many physicians took the stand that, inasmuch as the management of diphtheria and scarlet fever cases was left to them anyway, and their course of action was the same, whether the case was reported and responsibility assumed, or the case was not reported at all, there was no reason that they should bother with reporting the case. Other physicians took the position that it was absurd for a health department to think that a physician who sees a case of contagious disease for fifteen or twenty minutes once or twice daily at the onset, and perhaps once a week during the convalescent stage, could guarantee that his instructions as to quarantine would be carried out. The physicians of this group would not put their signature to something they could not guarantee and still were not willing to placard the premises of their patients unless it was a general requirement. Another smaller group of our physicians reported their contagious cases and had premises placarded because they felt it a duty they owed the community in which they practiced that they should have knowledge of the location of all diphtheria and scarlet fever in their midst.

Under this system the laity soon came to feel that placarding was a reflection on their good citizenship, as indicating they could not be trusted to do the right thing without a warning sign on their door, while their next-door neighbor, perhaps much more reckless of life and the rights of others, had no warning sign. This feeling led them to beg their physicians not to have a placard posted, and, ultimately, to seek out that physician in the neighborhood who never had warning signs placed on the premises of his contagious cases. This sentiment among the laity helped the majority of physicians who never reported their cases, and also that large group of physicians who "assumed responsibility," whereas the small group of physicians who were doing the right thing as measured by standards set by all progressive municipal health boards found their practice curtailed with resulting financial loss. The plan of "assuming responsibility" was, in my opinion, the greatest millstone to progress that could be tied about the neck of any municipal contagious disease bureau.

By Jan. 1, 1907, the situation as regards scarlet fever was alarming and as regards diphtheria threatening. During the preceding year just closed diphtheria reports had almost doubled and more than four times as many cases of scarlet fever had been reported by about the same group of physicians who had done the reporting in previous years. This probably meant a marked increase in the number of these two diseases and that less than one-half the cases were reported, and yet delegations to

* Read in the Section of Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

the bureau of contagious diseases were frequent and insistent that something be done to protect their communities where localized epidemics existed. Many of the medical profession were in a measure hostile, as they had come to feel it their prerogative to have charge of quarantine and other restrictive measures. The laity, too, resisted placarding of their premises.

The bureau of contagious diseases, forced to a "do-nothing policy" for want of men, was already greatly overworked. Records were in a chaotic condition. The office force was absolutely inadequate to handle a normal situation. Unavailing had been all efforts to convince those in authority that, in many respects, a contagious disease bureau is an emergency service just as truly as is the fire department, and that to cope with contagious diseases it is just as important that a large city have a specially trained and adequate contagious disease bureau force, if lives are to be saved and financial loss averted, as it is that she maintain a well-equipped and well-manned fire department for protection of lives and property.

Early in January, 1907, the threatening epidemic of scarlet fever broke forth and on January 29 reached its height as regards the highest number of cases reported in one day, with 413 reports. Our common council finally took the situation in their own hands and speedily provided for 350 men, nearly all physicians, 100 more than the number asked for by the contagious bureau, with whom to combat the epidemic. This was largely a milk epidemic.

It was February 1 by the time these raw recruits were instructed and competent to do work that would bring results. The cases decreased almost one-half in February over January. March saw a decrease of about one-half as compared with February. By April the situation was well in hand.

During the excitement incidental to the epidemic a level-headed councilman, stimulated doubtless by some progressive physician who realized the evils and handicap of "assuming responsibility," had passed an ordinance making it compulsory and mandatory on the health department to placard all cases of scarlet fever and diphtheria. With the lessons of an epidemic fresh in memory, and with the aroused public sentiment and a united press demanding safeguards against future epidemics, the prospects for better regulations as regards scarlet fever and diphtheria were bright indeed.

THE PROBLEMS FOR SOLUTION

Some of the problems left for solution by the 1907 epidemic were the following:

PROBLEM 1.—How to keep alive the aroused public sentiment to the point where press and public would demand a properly organized and manned contagious disease bureau that should pursue as progressive, as wide-awake and as aggressive an attitude towards scarlet fever and diphtheria as it did towards smallpox. This first problem was, fortunately, completely solved when in April, 1907, Chicago was given a progressive, fearless, energetic and thoroughly competent Commissioner of Health, respected by the medical profession of Chicago, her press and public generally. The press and public, guided largely by Dr. W. A. Evans, the Commissioner of Health, has certainly demanded a live, vigorous policy of the Contagious Disease Bureau ever since.

PROBLEM 2.—What immediate safeguards were needed for prevention of future epidemics? The following had been advocated for years by Dr. Spalding, the chief of Bureau of Contagious Diseases, and seemed desirable:

- A. Increased number of medical inspectors.
- B. A systematic, unified field inspection service.

C. Reorganized methods of keeping contagious disease records.

D. School inspection for contagious diseases.

E. An increased office force, work better systematized, and a full day's work demanded.

F. More accurate office data as to location of cases.

A. *Increased Number of Inspectors.*—One hundred medical inspectors were asked for and secured within one month, and they have ever since been a permanent part of our force.

B. *A Systematic Field Inspection Service.*—This was obtained by dividing Chicago's 190 square miles into 100 districts and assigning a medical inspector to each district. He is made responsible for the contagion and other conditions in his district. A definite territory to each inspector makes much less duplication of work. This field work is fourfold: (1) inspection; (2) investigation; (3) vaccinations, and (4) diagnosis.

1. By inspection we mean the proper handling of a case of contagious disease regularly reported by the attending physician. An inspection implies:

- (a) If diphtheria, a diagnostic culture, also antitoxin for patient and contacts.
- (b) Placarding premises in front and rear.
- (c) Establishing a strict quarantine.
- (d) Definite oral and printed instructions to family as to quarantine requirements.
- (e) If good quarantine is impossible, leaving a note for ambulance driver and order to hospital.
- (f) If diphtheria, and case is to go to hospital, culture contacts.
- (g) Leaving card of instructions for quarantine officer back of front door placard, giving him definite, concise information as to the quarantine requirements laid down by the medical inspector.
- (h) Notification to principals of schools attended by children in building of case of contagious disease and also to principals as to who, if any, from building infected, may safely attend school.
- (i) A complete written report to the department of each case inspected, embodying a statement of above and other facts, such as name of milkman, source of infection, school and room attended, etc.

In 1909, 49,952 inspections were made by medical inspectors. During the first five months in 1910, there were 27,693 inspections.

2. Vaccinations, in case of smallpox exposures and contacts, includes following up cases to see if vaccinations are successful and a watch for symptoms of smallpox. If symptoms develop, then prompt removal to Isolation Hospital.

3. Investigations are made of suspected cases learned of from all sources other than through the attending physician. Inspector is required to examine case carefully and if contagious, report to the department, quarantine, placard, etc.

In 1909, there were 23,141 investigations by medical inspectors. In 1910 to June 1, there were 2,216 investigations by medical inspectors.

C. *Reorganized Methods of Keeping Contagious Disease Records and Files.*—Instead of using the card-index method with a separate file of each item relating to a case, which required us to look in five or six different places before we could get complete data on the case, it was decided to use the envelope-filing method. This enables us to keep all data relating to case where we can refer to it quickly in its entirety. This change was of great value to both office force and public as to economy of time and convenience.

D. *School Inspection for Contagious Diseases.*—This is probably the most valuable single factor that Chicago has in the prevention of spread of contagion through the pupils of her 400 schools. This plan calls for a daily systematic inspection as follows: (1) A superficial routine examination of all pupils at opening of schools in fall; (2) all pupils who have been absent for more than three days before entering the class-room; and (3) any child referred to inspector by principal or teacher as suspicious.

How valuable this is in preventing diphtheria and scarlet fever is self-evident when it is explained that out of 537,590 pupils examined in 1907, 633 cases of diphtheria and contacts,

many of whom were undoubtedly "carriers," were halted at the threshold of our schools. In scarlet fever the figures are even more convincing; 1,456 cases of scarlet fever and contacts were excluded from our schools.

A summary since 1907 follows:

SCHOOL MEDICAL INSPECTION FOR CONTAGIOUS DISEASES					
Examined.		Diphtheria.	Excluded.		
			Con- tacts.	Scarlet Fever.	Contacts.
1908	499,046	178	180	278	254
1909	647,842	47	292	189	581
1910, to June 1....	262,645	14	136	92	233

E. *Increased Office Force.*—The office force was more than doubled, the work was carefully systematized and a full day's work demanded.

F. *More Accurate Office Data.*—Daily spot maps, made by months, were installed so that those in charge of contagious diseases might see at a glance the location and grouping of the cases of diphtheria and scarlet fever.

PROBLEM 3.—What measures were needed as additional safeguards against future epidemics? The following, among others, seemed very desirable and plans were laid to secure and put them into operation at no very distant date:

A. *Placarding and Instituting all Quarantine Measures More Promptly.*—To accomplish this, we go for our mail before 7 a. m., and have three clerks come one hour earlier than formerly. We sort, assign and telephone all assignments to the medical inspectors before 8:30 a. m., which is before they go out on their morning's duties. By this plan we often quarantine a case twenty-four hours earlier than formerly. We go for our mail Sundays and holidays and at once telephone out to the inspectors all diphtheria and scarlet fever cases for immediate action. This frequently means a saving of forty hours in instituting quarantine.

B. *More Strict Quarantine in Diphtheria and Scarlet Fever.*—To meet this requirement it was decided to separate the workers of the family from the patient and his attendants more completely. The plan adopted was that all adults of family who work out must live in a portion of the flat completely cut off from the patient and attendant, or if in a large house, live in a portion remote from patient and not come in contact with anyone who comes in contact with patient, or if these conditions were impossible of fulfilment, then the workers would have to room and board elsewhere or quit work and stay at home, unless they should elect to end the entire quarantine by sending the patient to hospital.

This plan works a hardship to a certain extent, but not as great as one would suppose. Very frequently the living-rooms are so arranged that by sealing one door the patient and attendant can be completely isolated from front part of flat and placards placed only on back door, so that the workers may sleep in front, but must take meals and find toilet facilities outside of premises. Our rule requires that the patient and attendant be given that portion of the house containing bath or at least toilet facilities.

To control the quarantine more effectually, a plan of espionage was devised. The disinfecter is to call every other day and watch for violations of quarantine. On his first visit he removes from behind the front-door placard a card which the medical inspector for him, giving concise instructions as to what quarantine shall be demanded. On his second visit he notes the date and quarantine conditions for the case, and, if he has a subsequent visit as well as mailing the department a report at each visit.

The quarantine officer is supplied with special forms filled out carefully and completely in case of any violation of quarantine, and this data is used by the health department or in other prosecutions. If his quarantine report is not satisfactory, the health department is forced to take action. If the case is one of diphtheria with a positive report of diphtheria, we immediately send the patient to the hospital. If the case is one of scarlet fever, we also do this. The room at Cook County Contagious Hospital where the patient is reported to be extended to the privilege of the public health department. We have been censured for maintaining first Annual quarantine requirements, but, personally, I prefer

for some slight financial hardship to one family for the sake of adequate protection of many families rather than the reverse, which was formerly often true, namely, that mothers would call, dressed in mourning, and blame us because their children had contracted diphtheria or scarlet fever and died through the carelessness of some person, made possible through failure of the department to provide the needed protection.

C. *A Corps of Medical School Nurses.*—Nurses are an indispensable adjunct to any efficient school medical inspection service, and the forty nurses whom we have, have added fully 50 per cent to the value of our school inspection service. These nurses were obtained and put to work Oct. 12, 1908.

D. *Scientific Handling of Diphtheria.*—Dealing as we were with a disease of definite etiology, with a specific therapeutic agent, if used early, and also amenable to transitory prophylactic immunity, our Commissioner of Health early decided that we ought to use accurate laboratory information as our basis for terminating diphtheria quarantine, instead of guesswork. Inasmuch as contacts are at times "carriers" and the cause of epidemics, it was necessary that our bureau should take cognizance of them. It was finally determined to require two negative cultures on consecutive days from patient and one from each contacts before raising the quarantine through disinfection.

It was also decided that we should get contacts immunized by acting through the attending physician if possible, but if he was indifferent, then through the medical inspector. These two measures have now long been in operation. Only since January 1 have we gone a step further and insisted on a diagnostic culture supplementing the clinical diagnosis. In all cases of diphtheria in which the attending physician has not taken a culture, the medical inspector is instructed to do so. If the first diagnostic culture is negative, he takes a second one, as statistics show that from 12 to 18 per cent of throats, when a negative result is obtained at the first attempt, will give a positive result when a second culture is taken. With two negative cultures from the throat and a written statement from our medical inspector that in his opinion the case clinically was not diphtheria, we send the attending physician the following communication:

Two cultures have been examined with negative results in the case of diphtheria reported from St., in person of On the enclosed card, please advise us of your wishes as to the disposal of case. Should quarantine be continued or terminated now? It terminated now, is disinfection desired?

The physician replies on a card of the following form:

Concerning case reported as diphtheria in the person of....., living at....., I hereby advise that

Quarantine be { Terminated. } Performed.
 { Continued. } And that disinfection be { Omitted.

Name....., M.D.,
....., who never had premises of his contagious cases. This sentiment among the laity helped the majority of physicians who never reported their cases, and also that large group of physicians who "assumed responsibility," whereas the small group of physicians who were doing the right thing as measured by standards set by all progressive municipal health boards found their practice curtailed with resulting financial loss. The plan of "assuming responsibility" was, in my opinion, the greatest millstone to progress that could be tied about the neck of any municipal contagious disease bureau.

By Jan. 1, 1907, the situation as regards scarlet fever was alarming and as regards diphtheria threatening. During the preceding year just closed diphtheria reports had almost doubled and more than four times as many cases of scarlet fever had been reported by about the same group of physicians who had done the reporting in previous years. This probably meant a marked increase in the number of these two diseases and that less than one-half the cases were reported, and yet delegations to

with an incubator. As a rule, it would not be in the police station incubator long before the time would arrive to send a messenger to the office of the chief of police and incidentally he brought along these cultures to the health department. It was also arranged to open the municipal laboratory earlier each morning and continue it later each day, with better service also Sundays and holidays. These improved conditions together with numerous free antitoxin stations, distributed over the city, made it easy for physicians to apply laboratory methods in diagnosing diphtheria and gave them no excuse for failure to use antitoxin.

G. Means of Making Our Health Ordinance More Effective.—This problem was solved by having passed by the city council certain rules and regulations to supplement the existing health ordinances, which, when passed, would have the weight of ordinances. These "rules and regulations" were passed Jan. 27, 1908, and have been of enormous value to us in enforcing health measures. Of these ninety "rules and regulations" at least twenty-eight apply directly to diphtheria and scarlet fever, and nineteen others indirectly touched on these two diseases.

H. Compulsory Reporting of Sales of Antitoxin by Druggists.—Recently we secured a law, long wanted, which compelled a druggist to report the sale of antitoxin. This reads in substance as follows:

An ordinance passed by the city council Nov. 1, 1909, requires all persons, firms and corporations to report to the Commissioner of Health within twenty-four hours any sale or gift of diphtheria antitoxin within the city of Chicago, giving the name and address of seller, buyer and patient; also the date and hour of sale and number of bottles sold, with number of units in each.

I. Means of Getting Diphtheria and Scarlet Fever Cases Reported.—From the time "assuming responsibility" was abolished, this problem was recognized as of great importance and plans were made to solve it. We were all agreed that physicians were not reporting their diphtheria and scarlet fever cases as generally as they should. Gradually, however, the physicians have taken to reporting their contagious cases, until to-day this problem is less complex and of less moment than formerly. A large majority of our physicians are pleased with the present methods of the department in the management of these two diseases. The very small minority who do not willingly report their cases of diphtheria and scarlet fever, do, nevertheless, report them because they realize that if they are detected concealing or "not reporting" a case of diphtheria or scarlet fever they are put to the inconvenience and expense of defending themselves in court for violating an ordinance, with danger also of having to pay a \$10 to \$200 fine. If a suit is started where there has been flagrant, almost criminal, negligence on the part of the physician it is given publicity in the newspapers. Also, if a conviction is secured, additional publicity is given.

As a rule it works this way: Suit is started, if a flagrant case, and the physician notified. He comes in alone, or with his attorney, to try to get the suit withdrawn. This is refused, but, on his promise to be good in the future, he is let off with costs and no notoriety in the public press. Less flagrant violations result in a letter to the physician asking him to call at the department and state his case, provided he thinks there are any extenuating circumstances which might cause the department to refrain from pressing the contemplated suit against him. Even this makes him trouble and elicits a promise to be good in the future. In still less flagrant violations, the department sends a form letter calling on the attending physician to make a statement in writing as to his relations with a case of diphtheria or scarlet fever said to have been "not reported" to the department.

This small percentage of physicians know that the Health Department is in earnest about demanding that they report their cases of diphtheria and scarlet fever. They fully realize that we have the public, press, charity and other organizations demanding reporting of these cases; also, 300 school principals, a small army of school and Sunday school teachers, a host of school pupils and the police department, in addition to the regular machinery of the department, chiefly the school nurses

and medical inspectors, all on the lookout for and ready to report hidden cases or suspected hidden cases to the Health Department.

This changed attitude of our people in three years is astounding and it is remarkable how often we hear from some one of these sources of the existence of a case of contagion before the attending physician's report gets to the department. Many physicians, slow in reporting cases in spite of the law requiring a report within twenty-four hours, are improving in this respect for the very reason that they fear that we will get the report from outside sources first, which will put them in the attitude of trying to conceal the case.

Another factor that makes for reporting of cases by the attending physician since school inspection was established, is the difficulty in concealing a case if there are school children in the family, as these children often tell of sickness at home and this leads to an investigation of the nature of the sickness by the school inspector.

If the patient is a school child, detection is still more certain when the medical inspector looks up absentees reported by school teacher as sick at home with sore throat or rash. Even if the case is not investigated, and after recovery the child tries to reenter school, the medical inspector then reviews the nature of the illness and if there are suspicious circumstances about the case, he sends the child home and goes to the home and makes a thorough investigation.

If facts warrant it, the child is told to bring a written statement from the medical attendant that illness was not of a contagious nature. More than once we have confronted a physician with his written statement that there was no contagious disease present, when he had used antitoxin, and the culture from a reddened throat showed the presence of the Klebs-Loeffler bacilli. A grilling for a physician under these circumstances, together with inconvenience caused him and his patient, makes him a convert ever afterwards to that group who report their contagious cases. Many physicians formerly crawled behind the excuse that it was only a suspicious case, that no positive diagnosis was made and, therefore, not reported. To prevent the obvious abuse of this plea, Rule 4 was added to our rules; this reads: "It shall be the duty of the physician who suspects one of the above named diseases, to report it as a suspicious case. Such cases will not be placarded or removed unless a warranting diagnosis is established. A corrected report of the case shall be made by the attending physician as soon as the diagnosis is made."

Another factor in inducing the physician to report is that the department learns of the name and address of the patient and the attending physician in every case in which the state of Illinois furnishes free antitoxin within the city limits of Chicago; also the law that if the physician or family buys antitoxin, the druggist is compelled under penalty to report at once to the Health Department such sale, giving names and addresses of patient and the attending physician.

All reports from state and druggists are looked up in our files and if the case is not regularly reported by the attending physician, an investigation by the medical inspector is made. Our index envelope records of physicians who do not report or cooperate fully with the department is often of value. If a physician gets into trouble with the department over not reporting a case, he invariably makes the plea that it is his first offence, and that, heretofore, he has always cooperated with the department to the fullest extent. Often we can meet this plea with documentary evidence of from two to ten instances in which he has not complied with the law as regards the minor contagious diseases. We estimate that we are now getting reported about 95 per cent. of all cases of diphtheria and about 93 per cent. of all scarlet fever attended by physicians.

METHOD FOR HANDLING LOCAL EPIDEMICS

DIPHTHERIA

The following is a good illustration of procedure in diphtheria:

A public school known as the McCosh Branch, consisting of four large school-rooms and one small class-room, had been remarkably free of all contagion from the time

school opened, early in September, 1909, and in this district no case of diphtheria had occurred in any family whose children attended this school.

On Nov. 1, 1909, three cases of diphtheria suddenly appeared in this district. On November 2 two more were reported and on November 3 three more cases. November 4, 5 and 6 each brought three cases reported among pupils of this branch. The evening of November 3 I communicated with Dr. G. M. Cushing, our medical inspector for that district, and instructed him to watch this situation, even if he had to neglect other schools. He stated that two factors were common in these cases. The patients all had the same milk-supply and all attended the McCosh Branch school. On November 4 a double investigation of the milk-supply by the medical inspector and food bureau excluded that as a cause. Dr. Cushing then took cultures from the throats of all the children in the school. November 4, 112 cultures from pupils of the three large rooms were sent to the municipal laboratory and on November 6 seventy-nine were sent in from the remaining pupils of this school.

The laboratory on November 5 reported that eight of the 112 cultures showed presence of Klebs-Loeffler bacilli. On November 6 the laboratory reported one positive result among the second lot of seventy-nine cultures submitted. All nine of the pupils with positive culture results were excluded from school, together with other children in these families. The entire school building was thoroughly disinfected. The school was not closed, although two or three delegations of excited parents demanded it. It is the policy of the bureau not to close schools; we believe in getting the pupils with contagious diseases out of school and then keeping the well children in school, where we can observe them daily.

Among the 112 which were examined and from which cultures were taken was one throat so suspicious that this child was sent home at once. The medical inspector followed soon after and found the following conditions, if my memory serves me right:

One child was dead with malignant diphtheria and two others gave unmistakable evidence of beginning diphtheria. The dead child had been attended for a week by a physician who had failed to recognize the nature of the malady, had given no antitoxin, and had permitted four children of the family to attend school. Another physician, called in as the child was dying, recognized the probable nature of the disease, used antitoxin, and no more deaths resulted.

Out of seventy-nine throats which were examined and from which cultures were taken on the second day was one so suspicious that the medical inspector took the child in his automobile to its home, with the intention of advising the parents to call their physician. On arriving he found an older brother, recently employed as a delivery boy for a near-by grocery, who had been sick for a week complaining of his throat. Examination showed a well-marked case of diphtheria. A sister, thoroughly exposed, was visiting in a near-by suburb, and when the medical inspector went to the address given he found her with a slight sore throat and brought her home.

A physician was called, positive cultures obtained, and all received antitoxin. Three of the four patients recovered, but the older brother developed a typical diphtheric paralysis and died on November 21.

Investigation in the homes of the other pupils whose culture gave a positive result revealed diphtheria clinically in one of these pupils, and when cultures were taken

from the throats of the members of the family a positive result was obtained from the mother, with a history of a probable mild diphtheria recently. The family physician reported and quarantined this family on November 6.

A second family called in a physician and the case was reported and quarantined. The remaining five, when visited, gave no evidence of diphtheria and members of the family, when cultures were taken, gave no positive result. Each child with positive cultures but no symptoms was immunized and placed under quarantine until two negative cultures were obtained, when he was readmitted to school.

Absentees from school were visited and cultures were taken, but no cases were found. After excluding the above cases on strength of laboratory findings not another case developed from these foci of infection in that school or in the district after November 9, and that little epidemic was at an end as soon as these cases terminated. This case is selected because of the small size of the school and the fact that it illustrates the various remedies used in combating diphtheria epidemics.

I know of no better illustration of the great value of laboratory methods. The laboratory told us accurately and quickly that the nine pupils in that school were a menace to 190 others. This elicited my admiration almost as much as did a demonstration a few years ago by Dr. H. Spalding, who, by inspecting the vaccinal status, was able to say which six of 250 people, thoroughly exposed for several days to smallpox in an institution, would contract smallpox; the six he picked out, and no others, did develop this disease.

SCARLET FEVER

The following, in a small way, shows the method of combating scarlet fever:

A neighbor complained to me that a child was attending a public school from a home where he believed there was scarlet fever. Our spot map showed a great many cases in this immediate neighborhood. The medical inspector of the district was asked to investigate the complaint, and found a child with scarlet fever in this home and no medical attendant. A child of the family in the "peeling" stage was found, not in the public school, as reported, but in a parochial school. A careful inquiry elicited the following: This child was sick at home for a week and then returned to school with a statement that he had been ill with a cold. The sister in charge, instead of having him examined by the school medical inspector, permitted him to enter the class-room without such precaution. The history was so typical of scarlet fever that no inspector could possibly have overlooked the diagnosis. Thirty-nine cases of scarlet fever occurred among the pupils of that school, due to failure of this school, in this instance at least, to live up to the requirements.

A plan of control given a trial in connection with the cases quarantined during this little epidemic worked so admirably that it was later attempted on a much larger scale. The plan was this: A disinfecter was detailed to call daily on the thirty-nine patients under quarantine and make them all take precautions against spread of contagion. Incidentally he disinfected premises whenever one of these cases terminated. The following extract of a letter written by me Feb. 18, 1909, to the medical inspector of this district shows the success in limiting the contagion to the original cases infected:

On January 30 we put a disinfecter in your district to watch the thirty-nine cases of scarlet fever and to maintain a strict

quarantine. Since then no new cases have developed and all but twelve of the old cases have terminated. It is necessary to remove the disinfectant to some other district. Please visit each of these remaining cases daily until terminated. See if you cannot prevent a new case occurring from any of these.

The following is another illustration of what can be done in efforts at prevention. A number of small children were exposed to scarlet fever in a nursery. These children were all in their homes before exposure was known to the health department. The name and address of each was secured, the family advised of the exposure, and each was kept under close observation by the medical inspector of this district during the period of incubation. In this way any cases developing were promptly recognized and placed under early quarantine.

The figures given in the accompanying tables seem to indicate a marked increase in the number of cases of diphtheria and scarlet fever in Chicago in the last two years.

TABLE 1.—CASES OF SCARLET FEVER REPORTED TO THE CHICAGO DEPARTMENT OF HEALTH FROM JANUARY, 1904 TO MAY, 1910

	1904.	1905.	1906.	1907.	1908.	1909.	1910.

Per cent.....	.151	.147	.129	.100	.104	.119	.132

We believe, however, that there have been no more cases in Chicago for the past two years than in 1904 and 1905. We are convinced that the cases are reported much better than formerly and that this accounts for the large apparent increase in the prevalence of these two diseases. Our reasons for this conviction are as follows:

1. Instead of a small group of physicians formerly on our records as reporting contagious diseases we now have hundreds of names of physicians not formerly in evidence there.

2. Figures show that the increase has been less in diphtheria than in scarlet fever, and this was anticipated, as diphtheria was always better reported than scarlet fever, because physicians could not well avoid reporting those cases in which they obtained free antitoxin and free examination of positive cultures at the municipal laboratory.

3. The increase in both diphtheria and scarlet fever reports has been about what we expected, as our machinery for compelling reporting has gradually improved.

4. We do not get one-tenth of the complaints we did in 1904 and 1905, accusing physicians of concealing cases.

It has always seemed to me that a comparison of death-rates for different years on diphtheria and scarlet fever is subject to great error. The virulence of the particular strain of micro-organism causing the disease often varies so greatly from year to year that there are bound to be marked fluctuations in the death-rate, just as in smallpox.

The physician who conceals the diphtheria or scarlet fever patient until dead will rarely certify the correct cause of death, and in my opinion many of these patients were formerly buried as dying of non-contagious diseases.

We do not get as high a percentage of cases of scarlet fever reported as in diphtheria and we are still greatly handicapped by not having a municipal hospital for scarlet fever. How badly we need this hospital is shown by the fact that in the past five months we have had 280 patients with scarlet fever in Chicago who were willing to go to the hospital, or else quarantine conditions were such that the patients should have been forced to the hospital.

Our requirement for period of quarantine in scarlet fever was formerly six weeks. We now send our disinfectant in one month, if the attending physician requests it. Occasionally we send him even a few days earlier than this, if the doctor furnishes us a written statement that he has inspected the patient carefully and is positive that desquamation is complete and no complications present. Our Rule 24, which says, "Physicians representing cases ready for house disinfection when they plainly are not ready will be prosecuted," prevents abuse of written special requests for early termination of scarlet fever quarantine by disinfection.

To our surprise, we find the percentage of cases as "peeling" no higher than when we held to a six-weeks period before sending to disinfect.

CONCLUSIONS

1. Chicago has made enormous strides in management and control of diphtheria and scarlet fever since 1907.

2. Safeguards against extensive epidemics of these two diseases are as complete and effectual as can be obtained at the present low per capita cost.

3. The department receives reports of almost all cases of diphtheria and scarlet fever seen by physicians.

4. School inspection, strict quarantine and hospitalization are the three most valuable assets as municipal safeguards against epidemics of these two diseases.

5. A campaign against diphtheria and scarlet fever to give results must be a daily, continuous and ceaseless battle.

100 State Street.

Sleeping-Sickness.—Professor Ronald Ross and D. Thomson have studied a case of sleeping-sickness in the former's Liverpool clinic for a period of seventy-three continuous days by precise enumerative methods and reported to the Royal Society, June 16 (*Nature*, June 23), the discovery of a regular periodic increase and decrease of the parasites in the blood. A variation from time to time had been previously observed, but the regular periodicity of their increase in every seven or eight days, observed by Ross and Thomson, seems to have been overlooked by other observers, probably owing to insufficient methods of counting.

WHAT CAN HEALTH DEPARTMENTS DO TO
CONTROL SCARLET FEVER? *C. HAMPSON JONES, M.D.
BALTIMORE

My attention was first attracted to the question by observing the marked contrast in the tracings of the cases and deaths due to scarlet fever and diphtheria in Baltimore. The record of cases reported of such diseases was available for only a few years, commencing with the year 1891 and ending with the year 1909, making a period of nineteen years.

Previous to 1891, the death-record alone gives us any information, and this has been reproduced in the tracings for the two diseases as far back as 1875, when our burial law requiring death certificates to be filed at the health department went into effect.

DIPHTHERIA

If, now, we consider the tracing for diphtheria (including croup) we find the number of deaths in 1875 was 238, which increased almost steadily to 929 in 1882. Then the number decreased year by year until the low number 206 was reached in 1889. Again the death-line rises year by year until 428 deaths are recorded in 1892, which was almost equaled in 1898 with 412 deaths, since which time the death line has decreased steadily until 1908, when only 64 deaths occurred. This decrease in the number of deaths of course was directly due to the free distribution of diphtheria antitoxin, which was commenced in 1895, but the use of this curative agent did not become general until 1898 and 1899.

The "case" line for diphtheria commences in 1891, when 1,031 cases were reported; it then fell, out of proportion to the number of deaths, to 346 cases in 1893; then it began to rise and in 1897 raised to 1,620 cases, which was 967 cases more than the year before, and continued to rise until 2,077 cases were recorded in 1898, since which time the number has decreased each year, with three exceptions (when there were 1,858, 1,461 and 1,172 cases respectively) until the low mark of 756 cases was reached last year.

The increase of recorded cases beginning in 1895 and ending in 1898, was undoubtedly due to three causes:

1. The return of the natural increase.
2. The opening of the Health Department Laboratory.
3. The distribution of free antitoxin.

The first cause probably has as a prime factor the increase of non-immunes.

The second cause was the use of the laboratory to assist in diagnosis, thereby acquainting the department with many cases that might not have been reported otherwise.

The third cause induced the people to submit more rapidly to the placarding of their houses in order to obtain speedy relief, thereby again increasing the number of reported cases.

The decrease of recorded cases since 1898, when there were 2,077 cases, down to 756 in 1909, was due to the following factors:

1. Free antitoxin.
2. Throat inspections by cultures taken by the health department before fumigation.
3. House placarding (commenced in 1898).
4. Fumigation.
5. Semiweekly notification of school teachers of cases, with

instructions to keep other children of the same house away from school.

6. Permits to return to school issued by the department only.

The number of reported cases, while showing a steady decline, yet remains higher than the number previous to 1898, due, we believe, to the fact that the use of the laboratory and the free antitoxin insures now the reporting of all cases of diphtheria, which did not formerly occur. Indeed, we have good reason for believing that many cases reported as diphtheria are not that disease.

SCARLET FEVER

Scarlet fever tracings are considered for the same number of years as the diphtheria tracings, and under the same conditions; i. e., the death line, commencing in 1875, and the case line in 1891.

Owing to the discovery of certain clerical errors in records previous to 1891, one should not place absolute confidence in the correctness of this scarlet fever "death" line, but there undoubtedly was, from 1875 to 1909 inclusive, a corresponding reduction (but probably not to the same degree) in the death-rate due to scarlet fever per 1,000 inhabitants in Baltimore, as occurred elsewhere. This reduction is shown in Table 1, originally published in a paper by Dr. Sidney Davies, which gives the record of the scarlet fever death-rate in London:

TABLE 1.—SCARLET FEVER DEATH-RATE IN LONDON PER
1,000 POPULATION

Year.	Death-Rate.	Year.	Death-Rate.
1861-1870.....	1.13	1895-1900.....	0.14
1871-1880.....	0.60	1901-1905.....	0.11
1881-1890.....	0.33	1906.....	0.11
1891-1895.....	0.24		

The probability that such a reduction in the death-rate per thousand of population is indicated by the small number of deaths in Baltimore due to scarlet fever from 1885 to 1909, inclusive, during which time the number of deaths varied from 85 to 11, except in the years 1891, 1892 and 1904, when there were 138, 258 and 143 deaths respectively.

The case-rate per thousand population, however, does not show so satisfactorily and we do not find any indication of a control of the number of cases such as is shown in the diphtheria record.

Commencing with 1891, the number of cases of scarlet fever reported each year was as shown in Table 2:

TABLE 2.—NUMBER OF CASES OF SCARLET FEVER IN
BALTIMORE

1891.....	1,512	1898.....	588	1904.....	1,212
1892.....	2,713	1899.....	434	1905.....	615
1893.....	406	1900.....	402	1906.....	577
1894.....	999	1901.....	391	1907.....	436
1895.....	775	1902.....	480	1908.....	1,312
1896.....	694	1903.....	1,224	1909.....	456
1897.....	928				

In studying this "case" line it must be borne in mind that some reduction in the number of cases reported since 1898 is due to the placarding of houses and to the school reports, because in 1898 we commenced to placard houses and added from time to time new regulations, and now we make the following requirements:

1. Placarding of houses.
2. Semiweekly reports to school teachers excluding all children in the infected house until released by the health department.
3. Fumigation.
4. Health department certificates permitting children to return to school.

Inasmuch as we have no counteracting influence, such as the giving out of a free antitoxin practiced in diphtheria, that would tend to reduce the reporting of all cases of scarlet fever, there probably are many cases not reported.

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

These four regulations, however, seem not to produce any lasting control, as evidenced by the "case" line from year to year. It is no doubt true that the regulations lessened the total number of cases each year, but not to such an extent as to warrant us in believing that they would prevent another epidemic like that which occurred in 1892.

The case-rate per thousand population in Baltimore during the past nineteen years was as shown in Table 3.

TABLE 3.—SCARLET FEVER CASE-RATE PER 1,000 POPULATION IN BALTIMORE

Year.	Case-Rate.	Year.	Case-Rate.	Year.	Case-Rate.
1891.....	3.10	1898.....	1.19	1904.....	2.28
1892.....	6.04	1899.....	.86	1905.....	1.12
1893.....	.86	1900.....	.79	1906.....	1.04
1894.....	2.06	1901.....	.75	1907.....	.77
1895.....	1.64	1902.....	1.91	1908.....	2.39
1896.....	1.45	1903.....	2.32	1909.....	.79
1897.....	1.91				

It appears also from this table that no real control of the disease exists.

As far as I have been able to compare other American cities with Baltimore, it is noticeable that in them also is the same want of control of the number of cases, even in those cities where the hospital accommodations for scarlet fever is provided and to a great extent used by the public. In this connection it is interesting to note that even in London, where it is said that nearly 90 per cent. of all cases are cared for in hospitals, there is a similar want of control. Table 4 is taken from Dr. Sidney Davies' article:

TABLE 4.—SCARLET FEVER CASE-RATE PER 1,000 OF POPULATION IN LONDON

Period.	Case-Rate.	Period.	Case-Rate.
1891-1895.....	5.3	1900-1905.....	3.6
1895-1900.....	4.4	1906.....	4.3

It would seem, therefore, that something more is needed than the four regulations above cited in common use in our cities, and the hospital isolation practiced in a few of them.

It is well known that the case mortality in scarlet fever during the last twenty-five years has been markedly less than in the previous years. In London this has been noticed since 1860, and this decrease in the mortality has been attributed to the improvement in sanitary conditions; but there has not been a corresponding decrease in the number of cases, although great reduction in the number has been produced by notification and isolation. It cannot be doubted that if notification and isolation were more rigidly carried out by physicians and health officials, a much greater reduction in the number of scarlet fever cases, or in other words, better control of the fever could be effected by health departments.

Why is it that a greater percentage of the cases are not reported? The following reasons may be given:

1. Mildness of attack, which results in many cases not being correctly diagnosed, and in many cases not being seen by physicians.

2. The opposition to house placarding among patients and their families for selfish reasons. Because of this opposition physicians do not report cases when they have doubt as to the correct diagnosis, and they give their patrons the benefit of that doubt.

3. The length of time a house is placarded or quarantined for each case. This difficulty is a serious one from the family's standpoint and we need very much enlightenment as to the length of time a patient is dangerous to others after the fever has disappeared.

If these difficulties are successfully overcome and proper isolation maintained, it is reasonable to believe that not only will epidemics be prevented, but the number of cases will be kept at the minimum.

To overcome the first difficulty, i. e., the "mildness of attack" two things at least are necessary—(1) proper instruction of the public; (2) proper training of physicians.

The Proper Instruction of the Public.—The method of giving such instructions will vary in different places, but the knowledge to be imparted consists of essentially two fundamental principles; (a) that scarlet fever, like all infectious fevers, may vary widely in severity, from an apparently simple sore throat to the so-called fulminating form producing death in a short time; (b) that all sore throats are communicable. We know of course that this is not strictly true, yet for practical purposes it makes a good working basis for the prevention of spreading disease.

The Proper Training of the Physician.—This consists, first, in an opportunity when a student to study clinically all so-called minor infectious diseases. A municipality should therefore not only make provisions for properly equipped hospitals for infectious diseases, but also should afford ample facilities for the instruction of students, because in the end the people are the gainers, not only by return to them of able physicians to treat such diseases, but also physicians who will more readily recognize such diseases in their milder forms.

The second difficulty, i. e., house placarding, is one that is at once overcome when all physicians are made to believe that in the end they are gainers by reporting scarlet fever promptly. Is it not true that there are but few physicians who do not dread being called on to care for such patients, and in consequence of such feeling are apt in one way or another to neglect them, thus causing increased danger to the patient and others.

The third difficulty, i. e., the length of time a house must remain placarded, is one that can be overcome only by more exact knowledge concerning the length of time that the scales of desquamation remain infectious. Until the germ of this disease is found it is impossible for department laboratories to assist the physician in raising the house quarantine until the desquamation has ceased, which frequently is prolonged to four, six, eight and even ten weeks. This long quarantine necessarily produces much hardship, especially to the poorer people who can least afford it, and also promotes ever-increasing carelessness as the weeks go by because of the difficulty of segregating children who are perfectly well although peeling and presumably dangerous to others. Dr. S. G. H. Moore, D. P. H. Medical Officer of Health, Huddersfield, in a paper on the subject¹ advocates the disregarding of the state of desquamation if all affection of the mucous membrane of the nose and accessory cavities has disappeared. By following this suggestion he reduced the duration of stay in hospitals from an average of 44.3 days to 29 days. His views in the discussions of his paper were antagonized by many, who, however, did not present facts to show how long the squamæ are infective. If, however, the desquamation period is dangerous throughout its entire length, or only in the earlier stages, it is important that all should recognize that the very mild cases of scarlet fever frequently show no desquamation even until near the end of the third week after the elevated temperature has disappeared. If the germ of

1. Public Health, London, 1908, xxi, 148.

the disease is in the squamæ of epithelium, it is obvious that the use of antiseptic baths during and after the febrile stage in all cases is indicated so that the danger may be reduced to the minimum should the quarantine be accidentally removed before desquamation has ceased.

All the difficulties that have been presented in this paper have, I fear, too much influence on health departments and cause them to exercise supervision over scarlet fever with much less enthusiasm than they do over diphtheria. I believe, however, that health officers can control the disease much more effectually under the following conditions:

1. If they endeavor to instruct the people through every channel of education that their protection for the present lies mainly in their own efforts; that they must consider all sore throats as dangerous to others; that the danger lasts during the entire period of desquamation; that this danger is lessened by antiseptic baths; that the infection of air-passages and accessory sinuses frequently continues longer than the period of desquamation; that isolation is the only means of preventing the spread of the disease.

2. If they urge not only the establishing of municipal hospitals for scarlet fever, but also advocate the early removal of all cases of the disease to it wherever proper isolation cannot be successfully established at the patient's home.

3. If they urge on the people correct information concerning the serious results, such as deafness, endocarditis, nephritis, etc., of even mild cases of scarlet fever.

4. If they urge on medical teaching institutions that medical students should not be granted diplomas until they have studied cases of infectious diseases under competent instruction.

2529 St. Paul Street.

ABSTRACT OF DISCUSSION

ON PAPERS OF DRS. RAWLINGS AND JONES

DR. B. FRANKLIN ROYER, Harrisburg, Pa.: I think that boards of health and public health officials lay entirely too little stress on the proper observation of scarlet fever cases at the end of quarantine and on proper inspection of the oral and aural passages. For a period of years when I had charge of the Municipal Hospital in Philadelphia we watched carefully the cases that were discharged and never had return cases come from homes where patients had gone that still had some desquamation about them, provided the nose and ears were healed. I believe that as a practical working basis it is well to continue quarantine until desquamation has about ended. In every case coming to the hospital after a previous case had been returned to a home we were able to find either a discharging nose or running ear in the discharged case. I am inclined to agree entirely with Cameron (who made a most important study in London of "return cases," publishing a splendid report covering 120 or 130 pages on the subject), that the peeling skin after a month of illness is not dangerous to the public. Nasal discharges and ear discharges are highly contagious a month after illness.

I wish we knew more of the methods of dissemination of scarlet fever. There must be some epidemiological factor that influences the prevalence of the disease as well as influences its death rate. Certainly it is true, if we study morbidity rates and mortality rates over a period of years, that we will find intervals of rise and fall, just as we find unusual prevalence of variola at intervals of about ten years. Some unknown influence permits it to get a foothold and some unknown influence changes its virulence.

DR. H. W. HILL, Minneapolis: I would like to suggest, with regard to the infectiveness of scarlet fever scales, the possibility that the scales of the hands, since they get on them the

discharges of the throat, may be infective by direct carriage of the mouth discharges, while scales not so infected may be—probably are—harmless.

DR. H. DELAMATER, Kansas City, Mo.: We started our medical school inspection this year with a limited number of inspectors, and the medical inspection of the public schools had a great deal to do with suppressing the epidemic. We had, I believe, in one month 123 cases of scarlet fever. In a territory which comprises several nationalities, there were about 7,000 school children. It was found impossible to make physical examination of all the children as we started to do. We could not successfully do so and keep track of the number of scarlet fever cases that would develop. Instead, when a teacher or principal of a school would report to one of the inspectors that little Johnny Jones had been absent from school for three or four days, the inspector would at once visit the home and inquire why the pupil was not attending school. Investigation proved in many instances that it was a well-developed case of scarlet fever that had never been reported to the health department.

The medical inspector would call up the attending physician and inquire if he had seen the case; if so, why he had not reported it to the department of health. By constantly keeping watch over these suspected cases, in this manner we managed in four schools with about 6,000 pupils to have one school (the Washington) in which the attendance is composed largely of Hebrew and Italian children, to have only eighteen cases of scarlet fever. In another school with a population of which 95 per cent. are Italians, we had six cases, and in one parochial school we had eight cases of scarlet fever. I am convinced that in order to control the scarlet fever epidemic, a close medical inspection must be made of the public school children. I believe in cases of scarlet fever, patients suffering from nasal discharge are often released too soon from quarantine, thereby causing great danger of infection to others.

Quarantine in scarlet fever, is in my estimation, a hardship on poor people. This phase of the subject has not been given careful consideration.

If quarantine is maintained for a period of from thirty days to six weeks, the wage-earner of the family will be deprived of his daily wages and his family of its support. This would make it impossible to secure the necessities of life, unless he appealed to charitable organizations therefor. During the past winter where a release was asked from quarantine in case of scarlet fever, before the regular quarantine period had terminated, instructions were given the medical inspector to visit each case and if he found an absence of desquamation and discharge from the upper air-passages, a disinfection of the home was ordered and a release issued.

DR. R. M. WINN, Hannibal, Mo.: In rural districts where we have no bacteriologic examinations, I should like to ask how long quarantine should be kept up after diphtheria and scarlet fever? Of course, there is no scientific way of determining that without a bacteriologic examination.

DR. G. KOEHLER, Chicago: In our experience in the Chicago Department of Health we frequently find diphtheria bacilli in throats of contacts that had been immunized with antitoxin. This method alone is not sufficient to prevent the spread of disease, if it is not combined with the making of cultures.

DR. SENECA EGBERT, Philadelphia: I would call attention to what Newman has said about milk being a carrier of both diphtheria and scarlet fever. Several epidemics have been traced by Newman to milk carriers.

DR. B. FRANKLIN ROYER, Harrisburg, Pa.: Are your inspectors permitted to release patients from quarantine if they have a discharging ear or a running nose?

DR. I. D. RAWLINGS, Chicago: One point in connection with Dr. Jones' paper. We find where we have discovered cases of scarlet fever in the "peeling" stage among the pupils in a given room at school, if the duration of the disease has been twenty-five or thirty days or more, and we expect a crop of scarlet fever, it usually does not materialize; but we do find that where a child with scarlet fever of perhaps a week's duration has gone back to school with throat and nose highly infectious, or early in the peeling stage, then we do reap our crop of cases.

Strict quarantine works a hardship to a certain extent, but not as great as one would suppose. Very frequently we can isolate the patient and the attendant with toilet facilities in the rear living rooms and by sealing a door and disinfecting the front portion of the premises, leave a place for the workers to live in front if they provide their meals and toilet facilities outside. If the family elect to send patient to hospital, they escape these hardships.

In reply to Dr. Hill's question, there was a time in Chicago when very few cases of diphtheria or scarlet fever were reported. Rather than not have reports, we thought it would be better to have a record of the case, even if nothing was done; so to obtain reports we allowed physicians to assume the responsibility of preventing the spread of contagion and did not placard, if the physician said he was willing to assume this responsibility. It did good for a time; we obtained reports and physicians were in a measure on their honor; they did their best to try to instruct families as to quarantine; but gradually there came a time when they would write in the word "assume" and forget the instruction part of it, and nothing practically was done.

As to duration of quarantine of scarlet fever, that is a mooted question. In Chicago we, as a rule, quarantine until they are through peeling and free of all complications.

We guard against milk epidemics by furnishing to the food bureau each day the name and address of the milkman in every case of scarlet fever and diphtheria. These are tabulated by weeks, and if there is found an unusual percentage of cases on any one milkman's route, the supply is immediately investigated.

DR. C. HAMPSON JONES, Baltimore: In my paper I attempted nothing concerning the methods of health departments to control the disease. I merely wished to call attention to our method and stimulate inquiry to improve by making our house quarantine method more exact.

Concerning diphtheria, permit me to say that this high point in diphtheria in the year 1898 was the time I took charge of the work. At that time the methods that were put into play seemed to produce direct results. In cases of diphtheria I do not believe there is any reason at all for an epidemic in a city where there is a good number of men in the health department to do the work.

Concerning scarlet fever, we practice what is extensively practiced elsewhere. I believe that we follow up the cases fairly well (that is, the reported cases); prompt placarding of the houses is practiced, instructions are given to the people, and the rooms finally fumigated; yet I don't believe that such methods will result in lowering scarlet fever as has been done with diphtheria, for the reason that the early conditions in the children with scarlet fever spread the disease before the department is notified. Time and again we have taken convalescent, desquamating children in the street playing with healthy children, yet there has not been a single case developed from them as far as we could ascertain. Why, I am not prepared to say.

THE RELATION OF MODERN DENTISTRY TO THE TUBERCULOSIS PROBLEM *

S. ADOLPHUS KNOPF, M.D.

Professor of Phthisiotherapy at the New York Post-Graduate Medical School and Hospital

NEW YORK

Fifty years ago there was really no dental science. The tooth-extractor of that day, picturesquely attired, with his long flowing hair, who went from town to town with a brass band and extracted teeth in the market-place, while in the majority of cases he was a shrewd business man and showman and knew human nature, very rarely had any scientific training or, if

he had it, he did not apply it to his calling. The preservation of the teeth and the tedious processes of filling a cavity and doing crown and bridgework were unknown to him. He did not care to preserve teeth, and the more he extracted the more lucrative was his business.

It must be said to the glory of American achievements that dental science, the art of preserving teeth by a truly scientific method, had its birth in this country. The European dentist has for the last twenty or thirty years looked to America as the Mecca of dental science. While we physicians have gone to Europe to complete our education, the European dentist comes to America to learn the best and latest in his art. In the capitals of Europe it is the American dentist who has the élite for his clientele, and many a crowned head has an American dentist attached to his court as *Leibzahnarzt*, and in not a few European universities Americans and graduates of American colleges of dentistry are the leading teachers in this branch.

The latest and the most glorious development of American dental science is dental hygiene. It is this subject which brings me to my main topic, for dental hygiene means prevention and preservation, and these bear the closest relation to the prevention of tuberculosis.

One of the earliest, and a very frequent symptom of tuberculosis is an impaired digestion. Now, while I would not wish to say that bad teeth constitute the only cause of these digestive disturbances, if bad teeth are present, they are contributors to these pathologic conditions. Ulcerated teeth may give entrance into the bone to tubercle bacilli accidentally inhaled, or as the result of secondary infection.

Since it is impossible to control dental hygiene except among children, and, may I also say, equally impossible to teach the subject to the majority of adults, modern preventive medicine has very wisely directed its attention to the children, and of course to those attending the public schools. It has been stated that, if New York children are typical of the school children of the United States, there must be in the schools of this country 12,000,000 children having physical defects, more or less serious, that should receive attention from parents and family physicians. Of the school children in New York City and in the United States there must be handicapped by malnutrition, 41,000 in New York; 1,248,000 in the United States; enlarged glands, 5,460,000 in the United States; bad teeth, 8,988,000 in the United States; defective breathing, 7,092,000 in the United States. Dr. A. H. Merritt informs me that recent investigations have shown that no less than 95 per cent. of the children in a public school are suffering from decaying teeth.

It is not within my province to speak to-night of the manifold medical, esthetic and even economic aspects of bad teeth in children or adults. I only desire to emphasize the great need of good, sound teeth in the prevention of tuberculosis on the one hand, and in the treatment of it on the other. The child or adult having good teeth will masticate his food properly and thus digest and assimilate it to better advantage. I have already said that we cannot reach the adult population, at least not nearly as easily as we can reach the children. It is for this reason that our local health department has very wisely created a division of child hygiene, with Dr. S. Josephine Baker at its head. The first thing to do, if one wishes to accomplish anything in the line of dental hygiene among children, is to instruct

* Read by invitation at the meeting of the Dental Hygiene Conference and Exhibit at the Metropolitan Life Building, New York City, May 16, 1910.

the parents; and to this end our New York Health Department issues the following leaflet and distributes copies freely to all parents through the children:

DEPARTMENT OF HEALTH
THE CITY OF NEW YORK

INSTRUCTIONS TO PARENTS REGARDING THE CARE
OF THE MOUTH AND TEETH

The physical examination of school children shows that in many instances the teeth are in a decayed and unhealthy condition.

Decayed teeth cause an unclean mouth. Toothache and disease of the gums may result.

Neglect of the first teeth is a frequent cause of decay of the second teeth.

If a child has decayed teeth, it cannot properly chew its food. Improperly chewed food and an unclean mouth cause bad digestion, and consequently poor general health.

If a child is not in good health, it cannot keep up with its studies in school. It is more likely to contract any contagious disease, and it has not the proper chance to grow into a robust, healthy adult.

If the child's teeth are decayed, it should be taken to a dentist at once.

The teeth should be brushed after each meal, using a tooth-brush and tooth-powder.

The following tooth-powder is recommended:

2 oz. powdered precipitated chalk.

½ oz. powdered castile soap.

1 dram powdered orris root.

Thoroughly mix.

This prescription can be filled by any druggist at a cost not exceeding 15 cents.

The child should take the tooth-brush and powder to the school and receive instructions from the nurse as to their proper use.

ISSUED BY ORDER OF THE BOARD OF HEALTH

To give an idea of the scope of the work of this department, let me give a summary of its work as far as dental hygiene is concerned.

The Division of Child Hygiene of the Department of Health, through its medical inspectors and nurses detailed to duty in the medical inspection and examination of school children, gives each child in the public schools a complete physical examination. This includes an examination of the teeth.

During 1909, 231,081 children were examined of whom 131,747 were found to have defective teeth.

Of these latter, treatment was provided through the dispensaries and private dentists of the city for 4,616 children, of whom 2,591 had fillings and 2,025 had extractions. Each child was thoroughly instructed in the hygiene of the mouth. Children are assembled in the schools, in groups, by the nurses and are taught the use of the tooth-brush.

These instructions are repeated at the home each time that a nurse makes a home visit for any purpose whatever. At these home visits the instructions are made inclusive, so that they may be taken advantage of by all the children in the family and especially by those who have not yet reached the school age. A copy of the above-quoted circular is given to each child in the school and left by the nurse at each home visit.

The circulars referred to are available for distribution by any agency in the city which requests the supply, and are at present in use in the schools of the Children's Aid Society and many of the other free schools of the city. This gives an idea of dental hygiene in its rela-

tion to tuberculosis as far as it can be accomplished among the pupils of our public schools.

The modern treatment of tuberculosis consists in the judicious use of fresh air, plenty of good food, plenty of good pure water inside and outside, careful regulation of rest and work and medical supervision. The proper feeding of the patient is one of the most essential factors. It cannot be done if the patient has bad teeth. It is very easy for us physicians to say to a patient when we examine him and find his teeth defective, "Have your teeth attended to." We say this daily to our poor consumptives, but I need not tell you why so many of them do not obey our instruction. There are very few free dental dispensaries in this city and the same may be said of many other cities; and many dispensaries require, and perhaps justly so, that the patient pay at least the cost of the material—amalgam, etc. We have in the greater city of New York alone from 40,000 to 50,000 consumptive poor. I do not believe that I exaggerate when I say that the majority of them need dental attention, and I know that it is a fact that only a very small minority get it. Some of our largest tuberculosis sanatoriums and hospitals in this city are without a dentist and all the dental work that is done is performed by the medical interns, and consists in extracting painful teeth. I do not believe that this is considered good dentistry in the light of modern dental science. Yet it is done every day. There are hundreds of the consumptive poor in our institutions who should have an entirely new set of teeth because they have but a very few bad teeth left; and still we say to them, "Chew your food well and eat plenty." How can we expect these patients to chew well and eat plenty of food and get well when they are thus handicapped in the most essential part of the treatment?

It was not my purpose in this paper merely to tell you of the relation of modern dental hygiene to the tuberculosis problem. I would be remiss in my mission did I not plead with you and particularly with men and women of wealth, to help us in the solution of this phase of the tuberculosis problem. One way to help is to create more dental dispensaries, and so to endow them that good work can be done, the workers paid, and the material furnished gratuitously to worthy patients. Every sanatorium or special hospital for consumptives should have one or several dentists attached to its staff according to the number of its patients, with a special well-equipped office, and an abundance of material needed for the efficacious treatment of all patients whose teeth need attention.

Here is certainly a field of true philanthropy and a splendid opportunity to serve a good and noble cause, and thus to be helpful in the attainment of that goal for which we are all striving—the eradication of the Great White Plague.

It is gratifying to note here that, following on the announcement of the Thomas A. Forsyth foundation of \$500,000 for the care of children's teeth in Boston, active steps in campaigns for oral hygiene are being taken in several places. The prevention of tuberculosis and other diseases seems to be the main object of the dentists. At a recent meeting in Baltimore the State Dental Examining Board and representatives of the Maryland and Baltimore Dental Associations decided to conduct an educational campaign on the care of the teeth. An exhibition will be held in June. At Rochester, the Dental Society of that city has just voted to work in close cooperation with the Rochester Public Health Association. Similar movements are being forwarded in Lynn, Brookline and other cities.

16 West Ninety-fifth Street.

FURTHER OBSERVATIONS ON THE MILK
SUPPLY OF WASHINGTON, D. C. *G. LLOYD MAGRUDER, M.D.
WASHINGTON, D. C.

At the meeting of the American Medical Association held in June, 1907, I had the honor of taking part in the symposium on milk, held in this Section. At that time I submitted some observations on the origin and progress of the movement for the betterment of the milk supply at the national capital. Attention was called to statements made in the "Report on Typhoid Fever in the District of Columbia,"¹ submitted by the medical society of the city to the House Committee on the District in 1894, and to the report of the Washington Milk Conference. This report was issued subsequently, Aug. 20, 1907, by the Department of Agriculture.²

Consideration of this subject is again desirable from the facts that national, state and municipal authorities have not yet fully realized the gravity of the situation; that many physicians still appear to be either ignorant or indifferent to the dangers, and that only recently at Washington, the National Association for the Study and the Prevention of Tuberculosis, in a series of resolutions regarding the pasteurization of milk showed itself loath to admit positively conclusive evidence of the communicability of bovine tuberculosis to man.

HISTORY OF EFFORTS FOR PURE MILK

Much interest was manifested in the presentations, which I made and great satisfaction was expressed that the officials and the scientific experts of the United States government had so actively joined in this movement for the improvement of the public health. I was so impressed with this reception of the work of the Washington Milk Conference that immediately on my return to Washington I sought an interview with Mr. Roosevelt, then President of the United States. At this interview I submitted the following letter:

In view of the agitation that is now going on in Europe and this country with reference to the question of the influence of milk on infant mortality, as well as the causation of tuberculosis, typhoid and scarlet fevers, and diphtheria, I would respectfully suggest that you direct the Bureau of Public Health and Marine-Hospital Service to make a thorough investigation of the milk industry in the District of Columbia from the farm to the consumer. For this purpose the Bureau should be empowered to have the cooperation of other departments of the government, and proper credit should be given for such aid.

Several foreign governments have recently ordered such investigations, and the reports are frequently quoted by writers in the United States on these subjects. These writers have expressed many divergent views.

The recent investigation conducted by the Bureau of Public Health and Marine-Hospital Service into the cause of the prevalence of typhoid fever in the District of Columbia, which report, including an examination of the milk-supply in the City of Washington, has been printed and will be issued in a few days, and the work of the Department of Agriculture concerning the milk-supply at the farms, have shown that many lives could have been saved and numerous cases of disease avoided by more careful attention to the health of the dairy-

man, as well as of the cows, and the handling of the milk at the farm, in transportation, and distribution in the city.

Much valuable information has been accumulated by both departments, which can be consolidated and developed so as to be utilized as a standard not only for the District of Columbia, but for the United States. This standard is very essential at the present time, and, with the facilities at the disposal of the United States government, should have equal weight with that of any other government.

It can be readily shown that much can be done to improve the milk-supply without materially adding to the cost of the farmer and thus to the consumer.

The report of such an investigation should be freely illustrated that it may serve as an educational document.

President Roosevelt had previously shown great interest in public health matters. He grasped the importance of the subject and immediately directed an investigation, which was conducted by recognized experts in the United States Department of Agriculture, the United States Public Health and Marine-Hospital Service of the Treasury Department, and Dr. W. C. Woodward, health officer of the District of Columbia.

These experts elaborated and endorsed in every particular the work of the Washington Milk Conference. Their report under the title of "Milk and its Relation to the Public Health," was issued in January, 1908, by the United States Treasury Department.³ A revised edition was issued January, 1910, as Bulletin 56. While this publication is one of the most valuable ever issued by the government on public health, its value would have been greatly enhanced had it been submitted to a conference of writers of the various articles and the advisory board of the Bureau of Public Health and Marine-Hospital Service. Then probably the statements would have been in greater harmony and the endorsement of such a distinguished body would have added greatly to its authority.

The movement for the improvement of the milk-supply in Washington seems to have two distinct periods, one from 1894 to 1907, the other from 1907 to date. It will be desirable to recall some of the incidents connected with this movement and the results that have accrued. The progress of the first thirteen years was great; that of the last three years has been marvellous. The work done in Washington has exerted an influence not only in this country but also in Europe. In fact, its influence has also extended to Australia.

At a public meeting on Feb. 5, 1894, called for the purpose of aiding in the improvement of the sanitary condition of the city of Washington, the late Dr. Charles Smart of the army read a paper on "The Causes and Prevalence of Typhoid Fever."

The statements made by Dr. Smart were so startling and of such damaging character to the prosperity of the city that I called the attention of the Medical Society of the District of Columbia to them at the meeting held on February 7 and moved for the appointment of a committee to consider the subject. Dr. W. W. Johnston, Dr. C. M. Hammett and myself were appointed as such committee.

It was found that the conditions were even worse than Dr. Smart had represented. The committee considered that there were four principal causes for the occurrence of the disease: (a) Potomac water-supply; (b) pollution of the soil by the leakage from privies, defective sewers and the backing up of sewage from tidal movements; (c) to drinking of well or pump water; (d) drinking of contaminated milk.

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Report on Typhoid Fever in the District of Columbia, submitted by the Med. Soc. of the D. C. to the Committee on the District of Columbia of the U. S. House of Representatives, June 14, 1894.

2. Sanitary Milk-Production. Circ. 114 Bur. Animal Industry. Dept. Agric.

3. Bull. 41 Hyg. Lab. U. S. P. H. and M.-H. S.

Among the recommendations of the committee, which were unanimously adopted by the medical society, were the construction of works for the filtration of the Potomac or Washington water—the only method of purification—the abandonment as rapidly as possible of all wells within the city limits; the repairing of defective sewers; the extension of the water supply and the sewers; the making of house connections to these.

The views of the committee as to the unhealthfulness of well waters were fortified by the results of bacteriologic examinations of water from thirteen wells in the city of Washington, made by Dr. J. J. Kinyoun. The water from nine of these wells was classed as bad, and from two as suspicious. It was recommended that the nine wells be closed and that the remaining four be kept under observation.

The influence of these two recommendations in the committee's report was immediately noticed:

9. Careful inspection of all dairies in the District from which our milk-supply is drawn, and the enactment of a law by which no milk shall be sold in the District without a permit from the health office. The inspection should cover an examination at the dairies of all possible sources of infection, including the water-supply.

10. The urging on the members of the profession of a careful collation of all facts bearing on the mode of infection in each case, and the advantage of reporting such facts to the society, and the propagation of the doctrine that immediate disinfection of the stools is the first duty of the physician as guardian of the health of the community.

It will be seen that pure milk and pure water, both in the city and at the farm, and the avoidance of contact with persons suffering with the disease, were the cardinal preventive measures recommended. The importance of these recommendations was immediately recognized. The United States Congress, as well as the city authorities, sought the aid of the medical society and individual members in framing remedial legislation.

That the recommendations made in 1894 were important and proper is attested by remarks made at the symposium on the causes of typhoid fever in the District of Columbia, held, on my motion, by the medical society, Feb. 19 and 26, 1908. Dr. George M. Kober, professor of hygiene, Georgetown University, said that "every point developed in recent discussions, save the influence of domestic filters and water-coolers, had received consideration before." Dr. Kober's investigation in 1895 confirmed in every particular the conclusion reached by the committee of the medical society in 1894, and developed two new facts, viz., the percentage of imported cases and the agency of flies in the transmission of the disease. Dr. William C. Woodward, health officer of the District of Columbia, said that the problem "Why is typhoid fever more prevalent in the District of Columbia than in other communities?" was clearly the problem before the medical society in 1894, when it inaugurated the campaign against the disease, and the clear realization of the problem to be solved contributed very largely, no doubt, to making the work of that committee as thorough and the results as complete as they were." It may safely be said that, aside from the one or two new facts brought to light by Dr. Kober's investigations, to which Dr. Kober has referred, no material fact has been disclosed by any subsequent investigation that was not anticipated in the report of the medical society.

The contention for pure water, pure milk, and the avoidance of contact, outlined in 1894, as preventive measures against typhoid fever is further sustained in

Bull. 44 of the United States Public Health and Marine-Hospital Service,⁴ as follows:

Thus far our studies indicate that typhoid fever will cease to be a problem in any community having clean water, an uninfected milk supply, and in which cases of the disease are treated as dangerous and contagious.

In drawing up the conclusions and recommendations of this report we have had the benefit of consultation with the advisory board of the hygienic laboratory, composed of eminent scientists and sanitarians. This privilege is appreciated and we desire to acknowledge the help we have received from the members of the board collectively and individually.

The first step toward carrying out the recommendation of the committee of 1894 was the passage of an act by Congress, approved March 2, 1895, which required the inspection of all dairy farms and a permit from the health officer of the District of Columbia before milk could be sold for consumption in the city of Washington. This requirement applied not only to the farms in the District of Columbia, but also to those in the states supplying milk to Washington.

CARD REGISTRATION OF DAIRIES

About this time Dr. W. C. Woodward was appointed health officer. He instituted the registration of the results of the inspection of the farms and depots on cards known as score-cards. Washington has the honor of being the first city in the country, if not in the world, to require inspection of the dairy farms as well as the milk depots in the city.

The use of score-cards has proved to be very popular as well as valuable. Many states and cities have adopted them. The United States Department of Agriculture reports that it has supplied them to about 300 cities in thirty-nine states, and that they are being widely used. The province of Ontario, Canada, has also adopted inspectors and the score-card system of recording such inspection. Previous to January, 1908, less than 50 cities had sought the cooperation of the Department of Agriculture in instituting inspection. These figures, however, do not represent the full extent of the use of the score-card system as it has been formally adopted by the state health authorities of fifteen states, and is being introduced by them in the cities under their supervision.

This inspection has revealed many unfavorable conditions both at the farm and at the city depot. In sanitary houses, milk houses and barns were common. The attendants on the cattle were careless of their personal habits and frequently were suffering from disease, sometimes of a contagious character. Cattle were frequently found covered about their flanks, legs, udders, and tails with manure and other dirt, which readily dropped into the pails while milking was being done. Cattle were many times found suffering from constitutional diseases as well as local affections of the udder. Flies swarmed about the premises. Frequently on the surface of the milk in the pails floated dead and dying flies. With the knowledge now available of the habits of the fly, this condition alone is a most dangerous source of milk infection. Dr. L. O. Howard in a recent publication by the Department of Agriculture suggests that the common house fly be known as the "typhoid fly." The presence of sediment in the milk containers was a common occurrence. This is especially dangerous, since it has been shown that the ingredients are pus cells, blood, epithelium, barn-yard manure, and

4. Bull. 44 Hyg. Lab. U. S. P. H. and M.-H. S., May, 1908, p. 9.

varied bacteria, including colon bacilli, and, as shown by Schroeder and Cotton, very commonly the tubercle bacillus.⁵

Few, if any, facilities were found for boiling the water to cleanse the utensils used in the handling and transportation of milk, the hands of the milkers, or the udders of the cows. Polluted water readily contaminates milk. This contamination rapidly multiplies at a temperature above 50 F. The knowledge which is rapidly being accumulated as to chronic carriers of the typhoid bacillus, and the common custom which prevails in rural communities of depositing human excreta on the ground, frequently in close proximity to residences, barns, and water-supplies, demand that the water-supply on dairy farms should be frequently examined and carefully guarded against contamination. The location of the premises for the storage and the handling of dairy products in the city depots was frequently most objectionable and at times entirely unfit for such purposes.

The following are some results of one year's use of the score-card system of inspection at Indianapolis:

Dairies scored, 717.

Barns improved, 381.

New barns built, 41.

Milk rooms built or repaired, 319.

Visits made by request to advise about constructing new barns or repairing old ones, 137.

The report of the official in charge says:

While at first we met with serious opposition, producer and dealer have become convinced that instead of persecution, the work is for their betterment.

Numbers have thanked us for insisting that they improve their conditions, stating that they do not see how they could have produced milk under the conditions they did.

The records of inspection as kept on score-cards show the result of intelligent inspection of the dairy farms supplying milk to Richmond from May, 1907, to May, 1908. The first inspection in May gave an average of 41.5 out of a possible 100; the inspection in April of the following year, twelve months later, gave an average of 72 for the same premises. This demonstrates a gain of nearly 100 per cent. for the year. The improvement was steady throughout this time.

In the annual report of the Richmond, Va., health department for 1908 the dairy inspector in his report to the chief health officer says: "The disposition among our dairymen to improve their plants is wonderful, and all speak highly of the work of the health department."

Washington city also furnishes an excellent illustration of the effects of intelligent inspection. The inspectors and the producer have learned to understand each other. Many of the farmers welcomed the criticisms and proceeded to remedy these defects, as it was found that much could be done at an insignificant outlay of time and money. Much higher scores were given in many cases on the second inspection. As a result of this educational inspection much milk is delivered to the distributing depots with less than 2,000 bacteria to the cubic centimeter.

At the meeting held Sept. 22, 1909, in Washington, of the Milk Producers' Association of Maryland, Virginia, and the District of Columbia, President Thomas in his address reminded the members of the association that the day was past when the milk inspector was "looked on as an irreconcilable enemy."

Such expressions show the spirit with which intelligent inspection is met. This educational inspection means much to both producer and customer. It contributes not only to the health of the families of both, but also to that of the dairy herd. It is a well-known fact that typhoid fever prevails to an alarming extent in rural communities. It has been found that it is two and a half times more prevalent in the counties of Maryland than in the city of Baltimore. Tuberculosis is also quite common in the country.

RESULTS OF INSPECTION

Inspection has worked well; it should be perfected and extended. It should be assumed by state and municipal authorities and not left to the enthusiasm of public-spirited physicians and other citizens. Washington has apparently had most satisfactory results from the requirements for inspection. Dr. W. C. Woodward, health officer of the city of Washington, D. C.,⁶ says:

The death-rate from diarrheal diseases among infants during the five-year period 1880 to 1884 was 162 per 100,000. During the next five-year period it was 168, and from 1890 to 1894 it was 175. In 1895 the milk law was enacted. From 1895 to 1899 the death-rate fell to 135; from 1900 to 1904 it fell to 109, and in 1905 it was only 104, and in 1906, 1907, and 1908 only 97 per 100,000.

In 1909 it fell to 72. It is gratifying to see that 405 fewer babies died in 1909 than in 1894, the year before the milk law was passed.

The diagram that accompanies Dr. Woodward's article (Chart 1) shows the above facts graphically.

MILK AND WATER AS AGENCIES

The improvement in the death-rate from diarrheal diseases, typhoid, malarial and typhomalarial fevers has also been very marked in the period since the enactment of legislation governing the milk supply, and especially so since the active movement for its improvement started in 1907. The title "typhomalarial fever" is no longer used in the classification of diseases. It is a question if the many deaths attributed to malarial fever should not be considered as typhoid. The data of the one are similar to those of the other. Chart 2 well illustrates these observations. The rate 33.2 from typhoid fever in 1909 encourages the hope that Washington with continued improvement in its milk-supply will soon attain a much lower death-rate.

The rate in 1909 would have been lowered had the hospitals had a more nearly normal death-rate. There seems to be a connection between the death-rate and the milk-supply of the hospitals. In 1909 there were 780 cases of the typhoid reported with 114 deaths; 70 of these deaths occurred in hospitals. With the normal death rate of 10 per cent. 36 lives should have been saved.

With the limit of safety of "inspected" raw milk fixed at 100,000 the following numbers of bacteria per c.c. were found in milk furnished to Washington hospitals: 2,000,000; 2,800,000; 3,500,000; 4,000,000; 5,000,000; 10,000,000; 10,000,000; 15,000,000; 50,000,000; 111,000,000.⁷

The mortality from typhoid in some Washington hospitals reached the appalling rates of 25, 20, 18 and 16 per cent., although a few have the normal death-rate of 10 per cent. But in only one instance was the German

5. See Bull. 99 and Circ. 118, Bureau Animal Industry, Dept. of Agric.

6. Bull. 41 Hyg. Lab. U. S. P. H. and M.-H. S.

7. See Bull. 41 Hyg. Lab. U. S. P. H. and M.-H. S., p. 431, et seq.

tions has drawn attention to the necessity of immediate study of the significance of streptococci in market milk.

The rapidly accumulating reports of outbreaks of typhoid fever resulting from milk infected by bacillus carriers have excited an increased interest throughout the world in the improvement of the milk supply. Dr. Biggs, like many others, has been so impressed with the danger from this source that he considers it almost impossible to secure a safe milk-supply without careful and repeated inspection, including complete and repeated bacteriological examinations of every one connected with the production and handling of milk. As a result of his report, covering this and other points, the New York City Board of Health has adopted an order requiring satisfactory pasteurization of milk used for drinking purposes.

In the fall of 1908 over fifty cases of typhoid fever in Washington, D. C., were traced to the supply of milk from a single farm. The owner was a bacillus-carrier. The supply of milk from this farm was stopped.

From the well-known prevalence of rural typhoid, the presence of bacillus-carriers, and the existence of contaminated water-supplies at many farms which can readily contaminate milk, it seems that milk is a far greater factor in keeping up the typhoid rate in Washington than a number of writers have been willing to admit. I have always contended that dairy products were the principal sources of the disease. In view of recent investigations, I reassert my position.

BOVINE TUBERCULOSIS

During the past three years extraordinary progress has been made in the study of the relation between human and bovine tuberculosis. The position of Koch that bovine tuberculosis is a negligible factor in the causation of human tuberculosis is no longer tenable.

The work of Schroeder and Cotton on this subject attracted universal attention. It was deemed to be of the greatest importance. The British Royal Commission to inquire into the relation of human and animal tuberculosis, confirmed these experiments in every particular, and so reported to the British Parliament in January, 1909, in its "Third Interim Report." Their report was based on the information obtained from these repeated experiments.

Influenced by this report the Board of Agriculture and Fisheries of Great Britain issued in May, 1909, "The Tuberculosis Order of 1909." This order provided that after Jan. 1, 1910, milk sold in Great Britain should come from tuberculin-tested cows, or should be sterilized. These two paragraphs from this order are very positive:

As your local authority are doubtless aware, the subject of tuberculosis in man and in animals, and the relations between the disease in human beings and in animals has been under careful investigation during recent years in this country and abroad, and various phases of the question have been inquired into by successive royal commissions. So far as regards the possibility of the transmission of the disease from affected bovine animals to man, the board are satisfied that it must now be accepted as a fact that tuberculosis is transmissible by the agency of milk used for human consumption. The Local Government Board concur in this view, and a bill was introduced in the House of Commons by the President of the Local Government Board on the 25th inst. designed, *inter alia*, to afford protection to the public health from the risk of the spread of tuberculosis by the means of milk used for human consumption.

In considering the question in relation to animals, the fact that the disease is communicable to man by milk has a ma-

terial bearing on the measures to be adopted. Any action which results in the reduction in the number of tuberculous bovine animals in the country must reduce the risk of the spread of tuberculosis amongst the community, and if it were possible to eradicate from this country the disease in animals, a material step forward would have been taken in the campaign against the disease in man.

The accumulated testimony on the communicability of bovine tuberculosis to man was greatly accentuated in a paper by Dr. W. H. Park, director of the research laboratories of the Health Department of New York, which he submitted in Washington, May 3, at the meeting of the National Association for the Study and Prevention of Tuberculosis.

In this paper he showed that 22 out of 84 cases of tuberculosis of children under five years of age showed the bovine type of tubercle bacilli. Dr. W. H. Welch noted that the cases reported by Dr. Park were not selected cases.

PASTEURIZATION AND STERILIZATION

Even though the danger of contracting tuberculosis due to bovine tubercle bacilli from dairy products can be eliminated, if we can obtain milk from healthy cows, there still remains the danger of contracting tuberculosis, due to human tubercle bacilli and other diseases from contaminated milk. Milk can be made safe, however, by the proper application of heat. There are two terms applied to the results of heating milk, pasteurization and sterilization. These two terms must not be confounded; the former is a process that requires the application of a much lower degree of heat than is effective for the latter. Sterilization means the killing of all the germs that may be present in milk. Pasteurization means the destruction of the disease germs that are of more common occurrence in it, such as those of tuberculosis, typhoid fever, diphtheria, etc. The investigation of General Sternberg, confirmed by Dr. M. J. Rosenau, especially, have shown that the common or pathogenic bacteria are unable to retain their life and virulence when they are exposed to a temperature of 60 C. or 140 F. for a period of twenty minutes, and that the value of milk as an article of food is not perceptibly affected by the designated temperature. Professor Kastle, of the University of Virginia, after extensive investigation, concluded that the designated temperature, maintained for a sufficient time to destroy the disease germs of common occurrence in milk, has no deleterious effect on its nutritive value. Thousands of children under the eyes of careful and competent observers have been reared successfully on milk so treated without the slightest signs of scurvy or rickets. Rowland G. Freeman has recently shown that such outbreaks have been traced to mixed feeding; that milk was an insignificant factor. His observations were strengthened by those of numerous observers in Europe. There boiled or sterilized milk was almost exclusively used. The temperature required for sterilization does destroy the enzymes and impair the nutritive value of milk. This emphasizes the necessity for a proper appreciation of the processes of pasteurization and sterilization.

It must be kept in mind that the advocates of pasteurization do not countenance the use of unclean or old milk; on the contrary, they insist that pasteurization should be applied, but simply as a measure of safety against the dangers from milk which no other precautions can obviate. Furthermore, pasteurization should be practiced under proper supervision, and that form of

so-called pasteurization which is to some extent commercially practiced, during which milk is heated to an unnecessarily high temperature for barely a fraction of a minute, should be emphatically discountenanced. Health officers should be provided with properly equipped laboratories to keep constant check on the output of pasteurizing plants. Progressive men engaged in the distribution of milk, cream, and ice-cream employ skilled bacteriologists. There are two noted instances in Washington where this precaution has been taken. The rarity of typhoid fever amongst the customers using this pasteurized milk and ice-cream has been marked. All milk, whether pasteurized or not, should be consumed as soon as possible after milking.

It frequently happens that properly pasteurized milk cannot be secured on the market. The observance of the following directions for the home pasteurization of milk, by L. A. Rogers of the Bureau of Animal Industry, can then be practiced:

Milk is most conveniently pasteurized in the bottles in which it is delivered. To do this use a small pail with a perforated false bottom. An inverted pie-tin with a few holes punched in it will answer the purpose. This will raise the bottles from the bottom of the pail, thus allowing a free circulation of water and preventing bumping of the bottles. Punch a hole through the cap of one of the bottles and insert a thermometer. The ordinary floating type of thermometer is likely to be inaccurate, and if possible a good thermometer with the scale etched on the glass should be used. Set the bottles of milk in the pail and fill the pail with water nearly to the level of the milk. Put the pail on the stove or over a gas flame and heat it until the thermometer in the milk shows not less than 150 nor more than 155 F. The bottles should then be removed from the water and allowed to stand from twenty to thirty minutes. The temperature will fall slowly, but may be held more uniformly by covering the bottles with a towel. The punctured cap should be replaced with a new one, or the bottle should be covered with an inverted cup.

After the milk has been held as directed it should be cooled as quickly and as much as possible by setting in water. To avoid danger of breaking the bottle by too sudden change of temperature, this water should be warm at first. Replace the warm water slowly with cold water. After cooling, milk should in all cases be held at the lowest available temperature.

This method may be employed to retard the souring of milk or cream for ordinary uses. It should be remembered, however, that pasteurization does not destroy all bacteria in milk, and after pasteurization it should be kept cold and used as soon as possible. Cream does not rise as rapidly or separate as completely in pasteurized milk as in raw milk.¹¹

CONCLUSION

If the lessons taught by these observations be heeded, a great step will be made toward the control of milk-borne infections. Dollars spent by the thousand for prevention will save millions needed for the care of those afflicted with disease, to say nothing of the days of suffering that will be avoided.

It can no longer be doubted that dairy products—and this term includes milk, cream, ice-cream, butter and cheese—are excellent vehicles for the dissemination of pathogenic bacteria. Outbreaks of typhoid fever, scarlet fever, diphtheria, sore throat, and intestinal disorders of children have been definitely traced to contaminated milk. The proofs of the danger of tuberculous infection from these products are accumulating daily. The opportunities for such infection are manifold. With the greatest vigilance on the part of trained inspectors and the greatest care on the part of the householder this infection cannot be entirely prevented. The house-

holder also has a duty to perform to protect milk from contamination after it has been delivered.

Of course the carrying out of the recommendations for the production and delivery of more sanitary milk entails additional expense at the farm and the city depot. But the receipt of a single additional cent for a quart of milk would justify many improvements by the producer and the seller. A single case of sickness or a funeral resulting from contaminated milk would cost far more than the slight additional price of better milk for a long period.

Under these circumstances there should be no question about demanding that milk should be produced under conditions that would entitle it to be entered under Class 1 (certified milk) or Class 2 (inspected milk) as prescribed by the Washington Milk Conference; or, in case it does not conform to the requirements for these classes, that it should be efficiently pasteurized (Class 3). This classification, prepared by Dr. A. D. Melvin, Chief of the Bureau of Animal Industry, and approved by the Washington Milk Conference, is more fully described in Circular 114 of the Bureau of Animal Industry already referred to. It is a classification that will give us, not bad, indifferent and good milk, but good, better and best milk. To produce milk under any of these classes rigid inspection is required.

The prices that must be charged for the first class make it almost impossible for the man of moderate means to avail himself of such milk. Class 2 can be produced at a lower price, but would still cost more than ordinary milk. Hence the masses must resort to the milk of Class 3. With the precautions suggested, they would reasonably be assured in the use of this milk of a safe and wholesome supply at but a trifling advance in the price.

Those who are interested in the improvement of the milk supply and who wish to obtain a comprehensive summary of facts bearing thereon, are advised to write to the Secretary of Agriculture at Washington, D. C., for a copy of Circular 153 Bureau of Animal Industry, issued April 28, 1910. The title of the circular is "The Dissemination of Disease by Dairy Products and Method of Prevention."

Stoneleigh Court.

ABSTRACT OF DISCUSSION

DR. WILLIAM C. WOODWARD, Washington, D. C.: After searching for a proper basis on which to determine whether or not we have achieved any substantial results through our milk inspection service, I selected deaths from diarrheal diseases only, among children under 2 years of age, and it is to those alone that the chart exhibited by Dr. Magruder relates. It is true, as Dr. Magruder says, that the method of milk inspection in use in the District of Columbia was original with a committee of the medical society of the district, on which committee I had the honor to serve. Working quite independently of anything that had been done previously, so far as we then knew, we devised it. Later, however, it came to my attention that as far back as 1873, the three food inspectors who were then doing duty in the District of Columbia had united in a formal report to the then board of health recommending this very method of inspection. This proposed method included not merely the inspection of the farms by the inspectors in the service of the then existing board of health, but included also the permit system, whereby one city or one state can control the situation outside of its territorial jurisdiction. Later, about 1884, one of my predecessors actually inspected some of the dairy farms supplying milk to the district. I mention these things so that honor may go where honor is due. Had these early workers had back of them such public sentiment as was created by the publication of the admirable report of

11. Circ. 152, Bureau Animal Industry, Dept. of Agric.

Dr. Magruder's committee, that first pointed out the probable sources of typhoid fever in the District of Columbia, their work would doubtless have continued. As it was it died utterly, even its memory having passed from the public mind.

Dr. WILLIAM H. WELCH, Baltimore: I think that a model demonstration exhibited in the national capital is significant and impressive, and likely to be productive of results to the rest of the country. Of course, we all realize, I think, that sanitary problems connected with milk are about the most urgent and perplexing, in many ways, of solution, of any. Some years ago in Baltimore we had made an endeavor, at least, to start the same sort of a campaign of education of the public regarding milk that we had attempted in regard to tuberculosis. It may not be known to all that the first tuberculosis exhibit was that arranged by Dr. Fulton in Baltimore. It was a great success there, far beyond any thing we dreamed of; and since then it was adopted elsewhere; but give him credit for that. We have attempted to do the same thing for milk, but it has not had the same response; but I think it is a good idea, and that possibly the time is now more suitable.

It may be that the large mortality in the hospitals is due to the poor quality of the milk used there; but there is a question whether the high mortality of those particular hospitals is due to the milk.

Dr. B. FRANKLIN ROYER, Harrisburg, Pa.: Members of this Section might be interested in the educational campaign undertaken by the Department of Health in Pennsylvania. Three years ago our health officers, the men who institute quarantine for us, placard and disinfect premises, etc., were trained for dairy inspection by placing suitable literature in their hands and by having them further instructed by the county medical inspector under whom they work.

At the present time all dairy farms in the commonwealth are inspected twice each year. In our winter inspection completed some time in March we reached a total of 55,000 farms and stables producing milk for sale to creameries, condenseries, cheese factories, wholesalers, retailers and for sale from individual dairies. The inspection up to the present time has not, of course, been done with the great detail practiced at Washington, and it in no way interferes with towns and cities that have already some system of inspection of their own. In fact, it is a campaign intended to reach the men who are handling the cows and stables and caring for the milk in the country. After the inspection is made circulars are handed these men describing conditions that should exist, emphasizing particularly the need for cleanliness of cows' flanks and udders, the need for excluding all forms of dirt from the milk and the importance of cooling it at once.

We are now sending letters to each producer calling attention to the insanitary conditions found. This work reaches far back into the country district where the initial infection of milk commonly begins.

We have a statute which makes communicable diseases reportable, typhoid included. On receipt of such report telling us of the existence of typhoid, diphtheria or scarlet fever on a premises from which milk is sold, our county medical inspector at once visits the premises and establishes the department's regulations for the control of the milk-supply. If such regulations cannot be established, the sale of milk is stopped or the stock is transferred to a neighboring farm.

Dr. WILLIAM EDWARD GRANT, Louisville, Ky.: As has been suggested, we look up to Washington; what governmental authorities order and advise has great influence throughout the entire country. I am acting as health officer for my city, and we are much interested in what Washington tells us. Through such influence, in part, we have been able to get every cow that produces milk for the city I live in tuberculin-tested. We had a hard fight to accomplish this and it took six to eight months of very earnest and constant endeavor. The health officers of the state first issued an order that no milk should be sold in our state that did not come from tuberculin-tested cows; and then the city health officer wrote a letter to each dairyman who sold milk in Louisville, telling him that after a certain date no milk would be permitted to be sold in our city that did not come from a tuberculin-tested cow.

At the same time an order was given that no new cows should be brought into the herd, unless they were tuberculin-tested; and that the dairymen should clean up their dairies and disinfect them according to methods suggested by the government at Washington. In that way we have improved the milk-supply wonderfully in our city; and have also interested our dairymen in keeping it improved. The education to them has been of great value. The fact is, I believe, the dairymen usually are glad to improve bad conditions, if we tell them how. They didn't know how; and they welcomed somebody who would come and say "This is wrong; and this is the way to correct it." Now we have dairy inspectors go to these dairies and see that the cows are properly curried, and the udders properly washed before they are milked, and the milk taken to a separate place and cooled; and we try to persuade our dairymen to bottle it at once and bring it to market in that way.

I think that bovine tuberculosis is very dangerous to children, but not dangerous to adults. The children in the hot weather are a good deal run down, no doubt, by the heat; and the germicidal power of the blood being lower, the germs find easy access and a location in the alimentary canal of infants, and in that way they become diseased. That is avoided in part by having none but pure milk distributed. "The Babies' Pure Milk Fund" is doing a good work with us, and we have also pasteurized and certified milk, and in this way see that the babies get only the best.

Dr. SENECA EGBERT, Philadelphia: A few years ago, when the newspapers of New York were advocates almost universally of pasteurization of the milk, if I remember rightly, Dr. Darlington, of the board of health, opposed pasteurization at the dairy, the objection being that it gave the consumers a false sense of security, since a considerable period elapsed from the time the milk left the dairy until it reached the consumer, and there was the possibility that in the time of transit the milk might be contaminated, especially if carelessly handled. It does seem to me that that objection can be made a very strong one—that the milk can be pasteurized, and yet, if the way be left open for careless handling on the part of the train men or the dairy dealers in the cities, that there is chance for danger there.

Another thing that I am glad Dr. Magruder mentioned was the fairness of giving the dairymen and milkmen—the producers—a higher price for the milk. It is unfair, it seems to me, for us to advocate this better milk, unless we are willing to pay for it. Any man who knows anything about farming, knows that it is a pretty hard thing to provide the things demanded—sanitary barns, good stock and all that—and then to get no more than 3 cents or thereabouts for the milk. We must educate the public to allow a higher price for the milk—see that they understand that that don't come into the category of things to be cheapened in the attempt to reduce the high cost of living. The question of inspection is the big question and I believe that we have yet to appreciate that in most of our large cities the cost of inspection is apparently prohibitive. It ought not to be, but we are not getting—at least, as far as the municipalities are concerned—as much inspecting nor as many efficient inspectors as we should have.

Dr. G. LLOYD MAGRUDER, Washington, D. C.: First in regard to Dr. Woodward's observation, I do not claim paternity of the idea of the inspection and permit system. I did claim and do claim that the report of the committee of 1894, embracing recommendation 9, quoted by me, directly caused the passage by Congress of the law giving this authority to Washington. Hence I think it is justifiable to claim the honor of being instrumental in the initiation of inspection.

As to Dr. Welch's observation, I said bad milk was probably the cause of the high death rate in hospitals. The lowest rate occurred where little milk was used. It is a great satisfaction that Dr. Welch has corroborated the statement that bovine tuberculosis causes from fifteen to twenty-five per cent. of certain cases of tuberculosis in children under five years of age.

In answer to Dr. Egbert's question, pasteurization should take place in the city under official supervision. I spoke of 50° F. as the danger line because of the rapid growth of bacteria in milk above this temperature. This prompts me to

mention the desirability of investigating the effects of freezing milk. I shall promptly take up this question with the Secretary of Agriculture. Three years ago the United States Consul at Chemnitz reported to the State Department that a German physician had recommended the transportation of milk in frozen blocks, since no deleterious influence was exerted by freezing. American officials caution against allowing milk to freeze. These divergent views interested me at that time. I sought without success to have them investigated at the Hygienic Laboratory. General Sternberg, chairman of one of the committees at the Yorktown Exposition, awarded first premium for milk to the Virginia Polytechnic School at Blacksburg. This milk was delivered partially frozen, after transportation 400 miles in jacketed cans.

The influence of this Section since 1907 on the milk problem has been so great that I thought it desirable to report what has been done in Washington. The symposium at Atlantic City in 1907 on the milk supplies of several cities received marked attention. The paper which I read at the symposium contained observations made by officials of the Bureau of Public Health and Marine-Hospital Service, of the Department of Agriculture, of the Health Officer of Washington, and of citizens in private life. Much enthusiasm was manifested at the information, which showed that the government authorities were so interested in milk and water supplies.

I had seen Mr. Loeb, Secretary to President Roosevelt, before I left Washington. Mr. Loeb stated that the President was opposed to a department of public health, but was heartily in favor of a bureau. On my return to Washington I saw President Roosevelt and reported the proceedings of the Association on public health matters. He showed marked interest. He directed the investigation of the milk supply as requested in the letter introduced in my paper. Many other valuable investigations along this line have been conducted since then by the government. Much of this interest is directly due to the impetus given to the movement in this section in 1907.

SCAB FORMATION IN THE NOSE ITS ETIOLOGY AND PREVENTION *

W. PEYRE PORCHER, M.D.

Visiting Laryngologist to the Roper Hospital; Lecturer on Laryngology, Charleston Medical School
CHARLESTON, S. C.

"When all is said and done the local therapeutics [of atrophic rhinitis] seems to reduce itself to a thorough cleansing of the nasal mucous membrane, and the use of any simple application is as effective as anything. The severer remedies do not seem to have any material advantages over the milder ones. I am afraid that we have no specific, but I hope that one may be found and that the future will not, as in the past, show more failures than success."

These words form the closing lines of an article by Dr. George L. Richards, and about express the prevailing opinion held by rhinologists in regard to the treatment and cure of atrophic rhinitis, or true catarrh; that is, the formation of large collections of hardened mucus in the nose. The atrophic process in my opinion may be more truly regarded as a result rather than a cause of the scab formation. Be this as it may, whether *post hoc* or *propter hoc*, we are sure, at least, that we have as a result large roomy nostrils, filled with gummy collections of mucus of a desiccating character and a nauseating odor. In the early stages of the disease the nostrils are not so roomy, nor do the scabs become so dry and hard; but they rapidly cover the turbinates and fill up the vacant spaces, apparently in successive layers, until the nose is more or less completely occluded. Such

is the picture which is presented to us in a case of true catarrh in the earlier stages, that is, before the nose has become hollowed out, as it were, from the accumulated scab formation and the atrophic or drying-up process which take places beneath them has gone so far as to leave the whole interior of the nose almost functionless, as far as normal secretion, the purifying and moistening of the air, the function of olfaction, etc., go.

Confronted with a case like this we are at once inclined to look to the hidden recesses of the adjoining sinuses as the "fons et origo mali." We do this because there must be a cause for the gummy change which takes place in the secretions. This problem has puzzled the scientific world up to the present time.

ETIOLOGY AND TREATMENT

The etiology of atrophic rhinitis is wrapped up in such an interminable maze of theory and conjecture that to give even a brief outline of it would amount almost to a historical investigation. Among the most prominent of the etiologic factors to which it has been attributed may be mentioned syphilis, inhalation of dust, tuberculosis, anemia and chlorosis, tobacco and alcohol, hypertrophic catarrh, effects of a previous purulent rhinitis and suppuration of the accessory sinuses of the nose, fatty degeneration of the infiltrated cells, the trophoneurotic theories, and finally, penetration of micro-organisms, Lowenberg's *ozenacoccus*, etc.

To trace in detail the origin of these theories would only be a needless tax on you. I will therefore state briefly that in 1896 in a paper on "The Treatment of Atrophic Rhinitis" which I read before the American Laryngological Association I reported a case which had been successfully treated with local applications of Lugol's solution in the nose together with large doses of the iodid of potassium and such operative measures as would open the accessory sinuses and give free outlet to all inflammatory exudates, pus collections, etc. An exhaustive discussion followed this paper and almost all the different methods of treatment since then have been based on that discussion. On account of the fact being noted that whenever inflammatory secretions from any portion of the lower respiratory tract came in contact with the external air, they became coagulated or gummy and finally hardened, generally with a more or less fetid odor. It seemed evident that practically the same process occurred with scab formation in the nose.

It was necessary therefore to select some drug which would maintain the fluidity of these secretions and thereby enable the patient to expel the accumulations and prevent the noisome odor. The well-known influence of potassium iodid in producing lachrimation and increasing the nasal secretion naturally suggested that drug as the most efficient for this purpose. It was found necessary, however, to give it in increasing doses until a very large amount was ingested daily before his desirable result was accomplished. Of course this amount varied greatly in different individuals. Many patients were found who would absorb from 600 to 900 grains a day before the nasal secretions would remain fluid and this without any noticeable ill effects whatever; in fact, on the contrary, the gain in flesh would be rapid and the improvement in the general health would be very marked. I desire to emphasize this fact and to state that in every case in which I have used these large doses, together with the operative treatment, the scabs have ceased to form.

* Read before the South Carolina Medical Association, April 19, 1910

RESULTS

The importance of the discovery of any method by which the formation of these scabs may be stopped by the therapeutic effect of any drug through the blood, together with such surgical measures as will assist in eliminating the morbid processes, will be recognized when I state that I know of no other process in the literature of the subject which has been credited with like results. In the gradually increasing doses up to the large amounts herein advised, there were but few of the well-known constitutional effects of the drug exhibited; no salivation, but little laceration, no apparent ill effects on the kidneys, and few or no symptoms of iodism on the skin. In the cases which I have reported there was no history or symptoms of syphilis. The only case in which there has been any return of the scab formation was that of a boy aged about fifteen, who had marked cardiac insufficiency. After a violent case of epistaxis with severe reactionary fever he was removed by his parents and further treatment refused. The drug was always administered with six or eight ounces of water taken after meals. In these extremely large doses it appeared to liquefy the blood and doubtless the same action took place on the coagula in the nose. Hare gives the maximum dose of potassium iodid as from 100 to 200 grains, but I have been informed of cases in which as much as 1,500 grains have been ingested daily without apparent ill effect. My custom has been to begin with 20 drops of a saturated solution and run the dose up rapidly until the secretions in the nose become so fluid that the scabs are easily expelled. During this time, however, I make every effort to open the sinuses as freely as possible so as to give free outlet to all inflammatory secretions.

We are all familiar, of course, with patients with constitutional syphilis who will not tolerate potassium iodid in any quantity. Hence the presence or non-presence of syphilis does not appear to influence the toleration for the drug in any way, and hence also the extreme toleration for it in the large doses above mentioned did not lead me to assign syphilis as the underlying cause. It has been a noticeable fact, however, that those who have the scabs in the nose are almost universally extremely tolerant of the drug. I am not prepared to say just what the underlying condition or diathesis in the blood is. It seems to be recognized by a great many authorities to be syphilitic in many instances, but it is certainly not so in a great number of cases, as mercury seems to have no influence on them whatever, even when pushed to the verge of salivation.

The following illustrative case of a patient recently under treatment I will report because of the gratifying result obtained, and also for its instructive value.

The patient was a young woman, aged 18, of Irish descent, with every appearance of the most robust physical health. Her complexion was of the peach-blossom variety and was without a blotch. Her family were all healthy people and had never shown any signs of the disease. Her father died of tuberculosis, but she herself weighed 150 pounds and showed not the least tendency towards that disease. She had had the scabs in her nose for about one year, and was not aware of any special cause which produced them, except diphtheria, which she had in infancy. I found on examination that both nostrils would become impacted with scabs daily, and that it was only with great difficulty that she managed to extract them. She was put at once on potassium iodid and ordered to increase the dose as rapidly as possible. The anterior ends of both middle turbinates were removed successively so as to give free outlet to all inflammatory secretions, and the ethmoid sinuses were carefully curetted. The nostrils were also thor-

oughly cleansed twice or three times a week with a solution of mercury bichlorid and sodium bicarbonate. It is very gratifying to report that after each operation, and as the patient became more under the influence of the iodid, the scabs rapidly lessened until she had scarcely any at all and would go for days without the use of the douche. Subsequently the scabs have entirely disappeared. The largest amount of the iodid taken was only 180 grains daily.

85 Broad Street.

REPORT OF A CASE OF ANEURISM OF CORONARY ARTERY *

WALTER R. HEWITT, M.D.

Resident Physician, St. Louis City Hospital
ST. LOUIS

This case is interesting, first because of its rarity. (On examination of the literature to date, I was able to find only three reported cases, this one making the fourth and being the only case that showed involvement of the right coronary artery); and secondly, because diagnosis has never been made ante-mortem.

Patient.—C. R., permit No. 6622, a negro man, aged 27, single, laborer, entered the St. Louis City Hospital Nov. 8, 1909. Dyspnea had extended over a period of four weeks, and there was slight edema of both ankles. Examination of the cardiac area revealed a systolic and a diastolic murmur at the base, a systolic and presystolic murmur at the apex and also a loud, rubbing sound over the entire cardiac area. There was no marked distress at this time. The patient's mother died of dropsy; otherwise family history was negative. He had rheumatism in the right shoulder several years previously. The patient smoked and chewed tobacco in moderation, consumed large quantities of beer and whiskey. He denied emphatically of having had syphilis, although he had gonorrhea several times. The present illness had begun three months previously with vague pains in the abdomen and left chest. The patient stated that he had felt ill ever since. During the last week or ten days his stomach began to swell, as he terms it, and two days previous to his entrance into the hospital he noticed that his legs were swollen and about this time he also had a cough.

Physical Examination.—Patient was of fair development and nutrition. Epitrochlear and postcervical glands were distinctly palpable.

Respiratory Apparatus: Respiratory sounds were loud and jerky in character. Vocal resonance was exaggerated over the entire chest.

Circulatory Apparatus: The area of cardiac dullness was greatly increased superiorly and to the right of the sternum and extended well beyond the left mammillary line. The apex-beat was displaced one inch to the left of the left mammillary line and was in the fifth interspace. At the base of the heart could be heard a seesaw murmur, which was conducted into the left axilla. At one time, a presystolic murmur was heard, but this murmur was not present at this examination. The radial pulses were regular and equal, but the volume was not very good. Edema of the legs had disappeared at this time, two days after admission to the hospital.

Digestive Apparatus: The abdomen was smooth and slightly distended. The liver dullness extended $1\frac{1}{2}$ inches below the costal margin in the right mammillary line. The left lobe was markedly enlarged. There was no pulsation anywhere about the liver. There was some dullness over the flanks, probably due to ascites.

Genito-Urinary Apparatus: The urine was amber, acid and clear; specific gravity 1015; it contained few epithelial cells and leukocytes.

Nervous system was negative.

Clinical Diagnosis.—Adhesive pericarditis, cor bovinum, endocarditis and multiple valvular lesions.

* Read before the St. Louis City Hospital Alumni Society, May 5, 1910.

Course of Disease.—Treatment consisted of elimination, cardiac stimulation and morphia. On November 28, twenty days after admission, the patient had a leukocyte count of 15,500. Repeated examinations of the sputum and physical findings had excluded tuberculosis. The patient at this time became very restless and complained of colicky pains in the stomach, especially well marked in the epigastric region. He assumed the knee-chest posture, as it seemed to relieve his pains somewhat.

On November 29 the patient complained bitterly of pain in the epigastric region in the median line. This pain had grown progressively worse during the past twenty-four hours. Palpation revealed a pulsating liver reaching down to the umbilicus. The pulsation was marked just below the ensiform cartilage. The patient assumed the knee-chest posture by preference. When seen on the morning of November 29, the patient was in great distress, the heart sounds being somewhat incoordinated. He soon became unconscious, with imperceptible pulse. He died quietly after vigorous stimulation had failed.

Autopsy.—This was held six hours after death. Rigor mortis was complete; body heat absent. There was slight distention of the abdomen, but no edema of the extremities. On making a longitudinal incision, there was a subcutaneous edema over the thorax and abdomen. About a liter of straw-colored, clear fluid was found in the abdominal cavity, but there was no peritonitis.

On lifting the sternum, it was found that the heart extended on the right side about 5 cm. beyond the middle line and reached the level of the second interspace. The apex was about two fingerbreadths to the left of the nipple line. The ascending arch of the aorta was dilated just above the aortic valves to the size of a goose-egg. Both auricles and ventricles were widely distended with blood. There were only 3 or 4 c.c. of pericardial fluid. Over the anterior surface of the right ventricle, there was a moderately fresh epicardial opacity, 3 cm. long by 3 cm. broad.

The left pleural cavity contained about 200 c.c. of blood-stained fluid, while the right pleural cavity contained about a liter of the same fluid. There were moderately firm pleuritic adhesions over both bases and the posterior surface of both lungs. The heart before being opened weighed 900 gm. After the expulsion of blood and clots, it weighed 600 gm. Both auricles and ventricles were filled with red blood and clots.

In the right interventricular wall there were two fluctuating dome-shaped tumors; one, arising just below the level of the pulmonary orifice, had a base 2.5 cm. and rose 1 cm. above the surrounding structures; the other mass was located a little below the tricuspid valve, about 3 cm. at the base, and was not so sharply elevated.

The overlying myocardium was grayish-yellow, with hemorrhagic spots scattered about the periphery. The pulmonary valve was free and translucent. The orifice measured 7 cm.

The left heart was dilated. The ventricular wall measured 6 cm. The mitral valve measured 11 cm. On opening the aortic ring, the knife passed through and opened a mass of old, brownish-yellow, friable thrombus at the site of the auriculoventricular margin. This thrombus was about 4 cm. in diameter and communicated directly with the right coronary artery, the opening to which easily admitted the index finger. The center of this thrombus was filled with fresh, currant-jelly-like blood-clot. The left coronary artery presented no anomaly.

The interventricular wall presented a slight bulging over an area that corresponded with the swelling noted in the right ventricle. The myocardium in this area was yellow and opaque. A few overlying vessels in the neighborhood were markedly congested. There was a marked yellow striation of the myocardium in the right ventricle, especially in the chordae tendineae, which microscopically showed fatty degeneration.

Above the aortic ring the aorta had a saccular dilatation 6 cm. in diameter with a depth of 3 to 4 cm. The wall of this aneurism contained secondary pockets, which varied from 1 or 2 mm. to 1 cm. in diameter. There was a marked thickening of the intima throughout the rest of the aorta, the surface being covered with rugae throughout the entire length of the aorta. The aortic ring measured 8 cm.

The abdominal aorta showed a regularly folded and thickened intima.

The left lung weighed 250 gm., the right 275 gm. Both were air-containing throughout and presented no areas of consolidation, although there was moderate dependent congestion.

Each kidney weighed 180 gm., was unusually firm, and of a dark wine-red color. The capsule separated easily. The cut surface showed a uniformly dark-colored cortex with distinct markings. The cortex was about 6 mm. in thickness.

The spleen was firm; its surface was smooth and dark slate-gray. The surface was firm and pulpy, was free, and the markings were distinct. It weighed 100 gm.

The liver was greatly congested and weighed 2100 gm. The cut surface showed a marked contrast between the fatty liver lobules and congested central vein.

The pancreas and adrenals were negative.

Anatomic Diagnosis.—Aneurism of the right coronary artery, thrombus of the coronary artery, acute necrosis of the myocardium, sacular aneurism of the aorta, fibrous pleuritis, pleuritic effusion, chronic passive congestion of liver, lungs, and spleen, and fatty degeneration of the heart.

THE STRAUSS REACTION FOR THE DIAGNOSIS OF GLANDERS*

B. L. ARMS, M.D.

Assistant Director of the Bacteriological Laboratory of the Boston Board of Health
BOSTON

Since Strauss¹ in 1886 discovered the fact that when material containing virulent *B. mallei* was inoculated into the peritoneal cavity of male guinea pigs scrotal lesions developed, the method which bears his name has been very generally used.

A positive reaction followed by typical organisms and a typical culture is unfailing evidence of the presence of *B. mallei* in the material inoculated, while the failure to obtain the reaction is not proof that the horse from which the specimen was taken has not glanders. Hill and Burr,² and also Frothingham,³ in 1901 called attention to the fact that frequently material from a horse which had glanders, as proved by autopsy, failed to give the reaction.

The bacteriologic laboratory of the Boston Board of Health makes free examination for any disease of a bacterial nature which is dangerous to public health. Our tests for glanders during the past four years have been respectively, 159, 208, 265 and 232, and of this number 301 or 34.4 per cent. were positive. The technic of examination is given in full that each step may be followed:

TECHNIC

Outfits consisting of a box containing two sterile swabs in a tube, together with a card with blanks to be filled out by the veterinarian, may be found at any of the culture stations, of which there are about fifty scattered over the city. After use, the outfits can be left at the culture station to be sent in by the regular station delivery, or, as is more frequently done, may be sent at once to the laboratory.

On receipt, about 3 to 5 c.c. of sterile water is added and the swabs are thoroughly soaked, then by rotation, together with pressure, against the side of the tube, most of the material is left in suspension: the swabs are now used to inoculate a potato, after which a smear is made to show the kind and number of organisms present. They are then put in a pail containing 5 per cent. phenol.

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Strauss: Compt. rend. Acad. d. sc., 1889, 108, p. 530

2. Hill and Burr: Am. Pub. Health. Assn. Report, 1901, p. 439.

3. Frothingham: Jour. Med. Research, 1901, No. 2, vi, 331.

With the suspension, two male guinea-pigs (those weighing at least 500 gm. being preferable) are inoculated intraperitoneally; one with 1 c.c. and the other with 0.5 c.c., unless there are myriads of organisms, or if streptococci are present, when half as much is used.

The reason for using two pigs is twofold, for frequently, as will be shown later, one pig will be positive and the other negative; and on the other hand, one pig may die of peritonitis, while the other will live and give the reaction.

All pigs under test for glanders are kept for a month, if negative, before a final report is made to that effect, although a tentative report is made at the end of a week.

All pigs under observation are examined at least twice daily for the first week, and when any change is seen the fact is noted on the card.

As soon as possible after the pigs show the Strauss reaction, autopsy is made, and all notes entered on the animal cards, which are then filed away with the original one filled out by the veterinarian. At autopsy, a culture is made from each testicle which shows a lesion, and when but one shows the reaction, two are made from that one, and smears are also made for microscopic examination.

SUMMARY

In summing up the work on glanders, I have first taken all the positives for the past four years, ending January 31, 1910, and second, all cases during the past year.

A summary of the 301 positive cases shows the following dosage:

Cases showing organisms and receiving 1. and 0.5 c.c.....	258
Cases showing no organisms and receiving 1. and 0.5 c.c.....	18
Cases showing myriads of organisms or streptococci, receiving 0.5 and 0.25 c.c.....	25
	301

The result of the cultures made directly from the swabs, on receipt of the specimen, follows:

Culture negative in.....	132 cases
Culture positive in.....	32 cases
No notation on card.....	8 cases
No growth.....	3 cases
A mould present in.....	126 cases
Total.....	301 cases

It is noticeable that swab cultures from nasal cases are very apt to be overgrown by a mould.

The value of the swab culture is apparent from the fact that of the 32 cases in which the swabs gave a positive culture, 11 showed no lesion in the pigs by the third or fourth day, so were inoculated with a suspension from the surface of the potato, and in each instance there was a marked Strauss reaction on the second day following, and autopsy showed the characteristic lesions with typical organisms microscopically, and typical cultures were obtained from the lesions.

The location of the lesions in the 301 horses from which the specimens were taken is here shown:

Nasal.....	133 cases
Other than nasal.....	155 cases
Both nasal and lesion elsewhere.....	2 cases
Location of lesion not given.....	11 cases
Total.....	301 cases

Table showing cases, dosage and result of swab cultures by years:

	1906.	1907.	1908.	1909.	Total.
Cases positive.....	51	75	93	82	301
Receiving 1 and 0.5 c.c.....	51	73	88	71	283
0.5 and 0.25 c.c.....	0	2	5	11	18
Streptococci present.....	2	1	7	10	20
Swabs positive, pigs positive....	2	3	11	5	21
Swabs positive, pigs negative...	0	2	3	6	11
Suspicious bacilli present in examination of smears.....	10	17	32	18	77
Followed by positive culture....	1	2	3	2	8
Followed by negative culture....	3	10	12	7	32
Overgrown by mould.....	5	5	17	9	36
Showing no growth.....	1	0	0	0	1

	1906.	1907.	1908.	1909.	Total.
Swab cultures negative.....	21	37	38	36	132
Swab cultures positive.....	2	5	14	11	32
Mould.....	20	30	41	35	126
No growth.....	3	0	0	0	3
No notation on card.....	5	3	0	0	8

During the year ending January 31, 1910, 232 specimens were examined for glanders. Of this number, in 193 instances the inoculation consisted of 1 c.c. and 0.5 c.c., while in the remaining 39 but half as much was used.

The life of the individual pigs together with dosage is rather interesting. In the 193 cases in which the pigs received 1 c.c. and 0.5 c.c.:

Both lived in.....	141 instances
The 1 c.c. pig died in.....	14 instances
The 0.5 c.c. pig died in.....	8 instances
Both died in.....	30 instances

In the remaining 39 cases, the inoculation was 0.5 and 0.25 c.c., and of these,

Both pigs lived in.....	15 instances
0.5 c.c. pig died in.....	8 instances
0.25 c.c. pig died in.....	4 instances
Both died in.....	12 instances

From the above will be seen the value of inoculating more than one pig, as in a total of 232 cases, there were 34 instances in which one pig died while the other lived. This is even more striking when we come to consider the individual pigs among the positive cases, as in only 33 instances did both pigs give a positive reaction.

For convenience I call the pig getting the larger amount the 1 c.c. pig, and the other the 0.5 c.c., even in the cases where they received 0.5 and 0.25 c.c.

Both pigs positive in.....	33 instances
1 c.c. pig positive, 0.5 c.c. pig negative in.....	20 instances
1 c.c. pig positive, 0.5 c.c. pig dead in.....	7 instances
1 c.c. pig negative, 0.5 c.c. pig positive in.....	8 instances
1 c.c. pig dead, 0.5 c.c. pig positive in.....	6 instances
Swab positive, pigs negative in.....	6 instances
Only one pig used in.....	2 instances

From this it appears that had the 1 c.c. pig only been used, but 62 positives would have been obtained, an error of 24 per cent., while had the 0.5 c.c. pig alone been depended on, there would have resulted but 49 positives with an error of 40 per cent.

Had a swab not been made, 6 cases would have been missed, an error of 7.5 per cent.

While the final positive result would undoubtedly have been obtained by submitting other specimens, it will be readily seen that this would have only been accomplished after a delay which in many instances might have exposed a number of horses to infection. In any large series of tests for glanders, lesions other than the typical Strauss reaction will occur, and a number of these were spoken of in a paper by the author⁴ before the American Public Health Association in Winnipeg in 1908, and a number have since occurred.

The period from inoculation to development of lesions varies considerably. Thus, of the 1 c.c. pigs:

6 showed well developed lesions on 2nd day
23 showed well developed lesions on 3rd day
13 showed well developed lesions on 4th day
3 showed well developed lesions on 5th day

Three on the 6th, two on the 7th; one on each of the following: 8th, 10th, 17th, 22nd, 28th, 31st, 34th, and two on the 25th.

Of the 0.5 c.c. pigs:

6 showed lesions on 2nd day
11 showed lesions on 3rd day
11 showed lesions on 4th day
10 showed lesions on 5th day
1 showed lesions on 6th day
3 showed lesions on 7th day
2 showed lesions on 8th day

One each on the 9th, 18th, 23rd and 25th days, respectively.

Of the delayed cases, i.e., over 7 days, but two had a typical Strauss reaction, and in but two other cases was

4. Arms: Am. Jour. Pub. Hyg., August, 1909, xix, 570.

there any testicular involvement, and in each of these one testicle was converted into an abscess, there being but a thin wall, the interior being creamy pus, and *B. mallei* being recovered in pure culture.

There was a tumor at the inoculation site in 6 cases; twice an inguinal gland was involved; once a tumor was found in the omentum and once in the mesentery. In these freak cases none is considered positive without a culture and animal test with a typical Strauss reaction.

Three things are required for the diagnosis of glanders: typical Strauss reaction, typical organisms from the lesion, and typical cultures.

While there is a marked variation in the *B. mallei* on artificial media, the organisms direct from the lesions are characteristic, taking the stain (Loeffler's M:B) irregularly.

CONCLUSIONS

1. In the diagnosis of glanders by the Strauss method it is better to use more than one guinea-pig.

2. Before inoculating it is well to make a microscopic examination as a guide to dosage.

3. A culture from the swab often aids in the early diagnosis.

4. Pigs should be kept under observation for a month, and if a lesion of any kind is present, autopsy should be performed and cultures made.

30 Huntington Avenue.

A NOTE ON THE TREATMENT OF PERNICIOUS ANEMIA

ALFRED C. CROFTAN, M.D.
CHICAGO

UNDERLYING FACTS AND PRINCIPLES

Disturbances of the gastric function, varying from mild degrees of dyspepsia to complete achylia gastrica, almost invariably precede pernicious anemia and accompany it throughout. Whether the anemia (remaining undiscovered) is primary, the dyspepsia secondary, or *vice versa*, it is generally difficult to decide, and I am strongly inclined to the belief from a study of many case reports and from personal observations that gastro-intestinal disorders in the overwhelming majority of the cases usher in the disease. One could consequently imagine such cases of pernicious anemia to be the result either of chronic undernutrition or of a gastro-intestinal self-intoxication resulting from perverted digestive secretion, or both.

The fact that not every case of chronic undernutrition or of autointoxication develops into pernicious anemia calls for the inclusion of some specific factor or factors of hitherto unknown character, possibly of varying origin, of which the bothriocephalus toxemia, for instance, would be a prototype. Even without postulating the cooperation of any specific toxemia it is well to remember that any chronic malnutrition invariably produces secondary anemia; and I believe that any so-called secondary, or simple, anemia can ultimately develop into a so-called primary, or pernicious, anemia, in so far as any profound and persistent change in the quantitative composition of the blood can merge into a qualitative change in the blood composition, whenever, namely, the processes of regeneration become exhausted and degeneration from overtaxation sets in. Here a varying individual factor must be included, that is not a biologic constant and that is incalculable.

Since I have been paying attention to the gastric function in every case of profound anemia presenting the morphological characteristics of the pernicious type, I have observed either complete achylia gastrica or exceedingly low degrees of hypochlorhydria or complete achlorhydria. Several of the cases referred or seen in consultation were originally, in fact, interpreted as carcinoma of the stomach, owing to the lack of gastric acid, the dyspeptic disturbances and the profound anemia.

Here then is a definite point of attack in the treatment of this disease, viz., the restoration of nutritive equilibrium by artificial means, and, by implication, the prevention, so far as that is possible, of abnormal or excessive intestinal decomposition. The following method, after trials in various directions and the employment of different dietetic schemes, has proved itself to be most efficacious, leading, as will presently be shown, to a symptomatic (?) cure within a very short time in the three cases in which it has so far been consistently tried. When I record that all the other patients with pernicious anemia who have come under my observation in the last five years, who were not treated in this way, are dead or not at all improved, the justification of this preliminary note will be recognized.

INTERPRETATION OF RESULTS

In interpreting therapeutic results in any case of pernicious anemia the greatest conservatism should be observed in two directions; namely, first, one should be altogether sure that one is dealing with a true pernicious anemia and not with a severe degree of simple anemia; second, one should be quite certain that any apparent improvement is not merely one of the spontaneous remissions that occur in so characteristic a manner in this disease, and quite independently of any treatment that may have been instituted.

The blood analyses to be recorded below, indicating in particular the appearance of degenerative types of blood cells, identify the cases as pernicious anemia in the present accepted sense. That the improvement was not due merely to spontaneous remissions is manifested by the fact that an upward turn occurred almost immediately in each case, was steady and progressive until normal conditions were attained in an astonishingly short time, accompanied by a striking gain in weight. The normal weight and the improvement in the blood condition have been maintained until the present writing, all of the patients being in an excellent state of health both in regard to their subjective sensations and their working capacity, as well as in regard to their blood. The gastric achylia or hypochlorhydria remain unchanged, and it is necessary to pursue a régime continuously appropriate to this deficiency.

PLAN OF TREATMENT

The treatment consists in the incorporation of the maximal amount of proteins administered in conjunction with artificial digestants to facilitate their assimilation in the gastro-intestinal tract and their proper absorption from the bowel. The diet consists in an abundance of meat, fish, eggs, milk, buttermilk, administered by mouth in a finely divided form and fed in comparatively small quantities at frequent intervals; so that the patients instead of receiving three large meals a day receive five or six smaller feedings in the course of the twenty-four hours. The selection of the particular kind of albuminous food and its mode of preparation depend somewhat on individual peculiarities that must

be studied in each case; tastes and dislikes, cravings, idiosyncrasies. Meats are given in the form of broiled; roast and stewed preparations, never fried; or as meat juices, raw or slightly heated meat jellies, "peptones," gelatins; eggs, preferably raw or soft boiled, in large quantities each day, a dozen if possible; milk and milk preparations of all kinds *ad libitum*, raw, boiled, as cottage cheese, or in combination with eggs as eggnog, etc. The addition of a little alcohol each day to the diet has been found of value rather on account of the food value and the "sparing" properties of the latter than on account of any stomachic or generally stimulating effect. Fats are given moderately, because, when administered in combination with abundant albumens, they are apt to coat the albuminous particles in the stomach and prevent contact with the artificial digestive juices to be administered. Enough cereals, bread stuffs and vegetables, fruits, all administered in a soft and finely divided form, are allowed in addition, to make up a palatable meal.

Such an over-diet in which albuminous foods predominate is given both by mouth and by rectum; per rectum in the form of predigested clysmata, together with sodium bicarbonate, a little sodium chlorid and pancreas, with about 10 drops of laudanum (the latter to reduce expulsive peristalsis); by mouth, either in the same way (without laudanum), or, preferably by far, with very large quantities of hydrochloric acid. Here it is necessary to experiment a little. One must look on the stomach in these cases merely as a sac with no digestive function and generally with reduced propulsive powers, and one can either administer hydrochloric acid with the object of artificially creating conditions that resemble the normal gastric digestion, or can ignore the gastric digestion altogether and by administering pancreas and an alkali, so to say, transfer intestinal digestion backward into the stomach. The former plan, if it can be carried out, is by far the better, for the HCl, in addition to being a powerful digestant of albuminous pabulum, acts as a deterrent to the development of an abnormal gastro-intestinal flora. Pancreas-alkali, on the other hand, rather favors intestinal putrefaction as indicated by definite urinary and fecal phenomena. The acid plan, moreover, more closely approximates the normal. The pancreas plan permits of a more liberal feeding, especially of carbohydrates and fats, but I have found that the albumens count rather than the other food classes, so that in the particular class of cases under discussion nothing is gained by more food variety.

THE ACID PLAN

All of the patients reported below were treated on the acid plan. They were given 10 to 15 drops of strong hydrochloric acid fifteen minutes after each feeding, and again thirty minutes after each feeding. It is useless to administer the dilute acid. Much prejudice is encountered, especially on the part of the druggist who fills the prescription, to the administration of such large quantities of strong hydrochloric acid, but no harm ever accrues from its use, provided enough albuminous pabulum is given at the same time. In order to prevent mouth irritation the acid is best given in mucilage water; I have never seen any advantage from the simultaneous administration of pepsin, and consider it superfluous. Rectal clysmata of the character indicated above are given twice a day, or, if some rectal irritation results, only once a day. They are needed only in the beginning; that is, for a week or so. Occasionally a patient cannot tolerate them at all; in such a case it is best

to omit them, only, however, after a persistent trial and after every attempt has been made to overcome the prejudice commonly existing against this form of feeding.

HOSPITAL METHODS

That this treatment should be begun in a hospital is self-evident. In the first place, the patients should be kept completely at rest in bed; in the second place, a trained dietitian is needed to prepare the food properly until the patient or his attendants have been taught how to prepare and administer the diet; in the third place the patient's blood condition, body weight and digestive function should be under daily control; so that the treatment may be arranged to suit individual peculiarities that may be discovered. More than a three weeks' hospital sojourn is rarely needed. Improvement rarely becomes manifest before the tenth to the fifteenth day; but from then on, in the cases observed so far, the improvement is rapid. There is often some discomfort in the beginning, and the hospital is the place to enforce persistence in a somewhat strenuous and not altogether agreeable plan, especially as all of the patients have been very irritable and cranky in the beginning and quite difficult to manage. And one of the most gratifying results observed early in the course of the treatment has been a change in their mood and spirits and disposition for the better as soon as proper nutrition was again fairly under way.

THYROID, ARSENIC

In addition to the above treatment the patients should have some thyroid extract, in doses varying from three to five grains of the extract, three times a day, by mouth or with the clysmata by rectum. I am under the impression, enforced by certain special studies in this direction to be reported on in another place, that the administration of thyroid materially aids in the assimilation of proteins. In deference to a venerable plan all the patients also received in the beginning some arsenic, given in the form of sodium cacodylate dissolved in normal salt solution in the dose of one grain every day intramuscularly. Patients previously treated with arsenic alone never improved particularly, so that arsenic is considered merely an adjuvant, that certainly can do no harm and may possibly do some good along directions that we do not fully understand. Iron was not given as a drug; an overabundance of this element being incorporated in the meat juice ingested.

SYNOPSIS OF CASE REPORTS

CASE 1.—Mr. K. M. M., referred by Dr. C. H. Wallace, of St. Joseph, Mo. Age 54. History of gastro-intestinal disturbances extending over several years. Rapid loss of flesh during last year. Entered Michael Reese Hospital Nov. 2, 1908. Pale, anemic, slightly edematous skin. Slight albuminuria, a few hyaline and granular casts. Temperature on admission 99.4 F. Gastric analysis after Ewald test meal shows complete achylia gastrica without motor insufficiency. Blood Analysis: Hemoglobin 30 per cent., red b.c. 1,180,000, white b.c. 7,400. Differential Count: Neutrophils 67½ per cent., lymphocytes 30 per cent., large mononuclears 0, eosinophiles 1 per cent., transitionals 1.5 per cent. Red Cell Morphology: Poikilocytosis, megalocytes, microcytes, megaloblasts, microblasts, a few nucleated red cells, polychromatic degenerations. Weight on admission 132½ pounds.

Treatment instituted as above. Left hospital after three weeks, Nov. 23, weighing 137½ pounds, a gain of five pounds. Albumen and casts disappeared from urine. No edema. Color, strength and spirits greatly improved. Blood Analysis: Hemoglobin 65 per cent., red blood count 2,600,000. No megaloblasts or microblasts, a few nucleated red cells; poikilocytosis

still present but less marked. Treatment continued conscientiously at home with steady improvement in general strength, and resumption of daily duties.

The following was the report of the blood examination at the expiration of 10 weeks: Hemoglobin 85 per cent., red b.c. 4,400,000, white b.c. 8,400. No abnormal red cells. No poikilocytosis. Increase in weight. Report on Feb. 9, 1910: "I am as good as ever." Weight in May, 1910, 147½ pounds.

The patient still continues the use of large doses of hydrochloric acid and is instructed to persist in its use indefinitely.

CASE 2.—Mrs. K. L. C., Kansas City, Mo. Age 49. Seen first with Dr. Golden at Mercy Hospital and referred to Michael Reese Hospital Sept. 14, 1909. History of increasing weakness, severe digestive disorders and great loss of weight within a year. Patient in a state of profound prostration and unable to be out of bed. Exceedingly pale and slightly edematous skin. Slight albuminuria without casts. Temperature on admission 100.2 F.

Gastric analysis after Ewald test meal shows complete lack of hydrochloric acid, very slight peptic power and a little blood. No motor insufficiency. Blood Analysis: Hemoglobin 30 per cent., red b.c. 1,384,000, white b.c. 6,800. Differential Count: Neutrophils 72 per cent., lymphocytes 22 per cent., large mononuclears 2 per cent., eosinophils 2 per cent., transitionals 2 per cent. Red Cell Morphology: Poikilocytosis, many megalocytes and microcytes, a few megaloblasts, polychromatic degeneration types. The weight of the patient on admission was 199 pounds.

Treatment as described above. Discharged from hospital after four weeks, weighing 133½ pounds, i. e., a gain of 14½ pounds. Albumin disappeared from the urine. Skin color florid and no edemas. Almost normal strength. Blood Examination: Hemoglobin 60 per cent., red b.c. 3,400,000. No megalocytes or megaloblasts or polychromatophilia. Slight poikilocytosis. White count 9,100, differential normal. Referred to Dr. Logan Clendenen, of Kansas City, Mo. Report from the latter Oct. 26, 1909; Hemoglobin 85 per cent., red b.c. 3,500,000. On Dec. 27, 1909: Hemoglobin 100, red cells 4,400,000. No abnormal morphology. Weight on Oct. 26, 1909, 146 pounds. This weight has been maintained to date, as well as the normal blood condition.

The following report was received from the patient in May, 1910: "I feel splendid, sleep well and have a good appetite. However, I am still taking the hydrochloric acid and would like to have you tell me if I must take it during the remainder of my natural existence." This query was answered in the affirmative.

CASE 3.—Mr. J. B., referred by Dr. I. C. Smith, of Stockton, Ill. Age 46. Entered Michael Reese Hospital Sept. 1, 1909. History of loss of strength and rapid loss of weight for the last seventeen months. Patient exceedingly weak, very pale and slightly edematous. Slight albuminuria and numerous hyaline and a few blood casts. Severe gastric distress with loss of appetite and nausea. Temperature on admission 100.4 F.

Gastric Analysis: Total acidity 9. Free hydrochloric acid absent. Slight degree of motor insufficiency. Slight peptic power. A few red blood corpuscles were found in the stomach contents.

Blood Analysis: Hemoglobin 40 per cent., red b.c. 1,800,000, white b.c. 8,200. Differential count normal. Red Cell Morphology: Severe poikilocytosis, megaloblasts, microblasts megalocytes, nucleated reds and polychromatophilia. Weight on admission 135 pounds.

Treatment as above. Discharged from hospital Oct. 2, 1909, i. e., after about four weeks, weighing 155½ pounds, a gain of 22½ pounds. Blood Analysis: Hemoglobin 75 per cent., red b.c. 2,400,000. Poikilocytosis slight and no other abnormal red cells.

Treatment continued at home with progressive gain in weight and strength and resumption of farming duties. Patient reported on May 12, 1910, weighing 157 pounds, and with an altogether normal blood picture.

FILARIASIS ON THE ISLAND OF GUAM

GEORGE B. CROW, M.D.

Assistant Surgeon, U. S. Navy

U. S. NAVAL STATION, GUAM

Two months ago I found filariæ in a stained smear of sedimented blood which had been drawn from one of the arm veins of a native at 10 a. m. Investigation soon showed that the filariæ were present in the skin capillaries only at night, except that occasionally one or two would be found in a specimen obtained as late as 8 a. m. and sometimes as early as 5 p. m. They were most numerous near midnight. In size, structure and movements they were like *Filaria nocturna*. Their presence in the blood drawn at 10 a. m. can be accounted for by the fact that a comparatively large quantity of blood was drawn (10 c.c) and from a large vein.

A systematic examination of natives from various parts of the island was begun at once. Up to date 244 persons have been examined and filariæ were found in the blood of thirteen. The blood was drawn at night, and generally between 10 and 12 o'clock. In most cases three fresh preparations were examined.

The accompanying out-

Map of Island of Guam

line map shows the number of persons examined from the various towns, with the results, and is probably a fairly accurate indication of the distribution of the infection. Practically all the natives live in the villages indicated. Most of them go out to their agricultural pursuits during the day, but return to the villages at night.

The island is 31 miles in length and has an average width of 7 miles. The population is about 12,000. Agaña has a population of 7,000; all the other places are small villages.

TABLE OF EXAMINATIONS

Name of village	No. of examinations	No. pos.	No. neg.
Leper Colony	30	0	30
Agaña	75	2	73
Asan	7	0	7
Piti	8	0	8
Sumay	15	0	15
Agat	21	0	21
Umatag	5	0	5
Merizo	6	0	6
Ynaranjan	58	11	47

One of those who gave a positive test at Ynaranjan is a Japanese who has been on the island for three years but lived in Agaña till one month before the examination. He came here directly from Japan and has never

lived anywhere else. The other twelve patients are natives. The two in Agaña who gave positive tests are prisoners and are confined in the same building. One of these lived at Ynarajan before being sent to prison, three years ago. The other prisoner has been confined for two years and never lived outside of Agaña. It seems fairly certain that the first prisoner was the source of infection for the second, as the disease is apparently closely limited to the region of Ynarajan.

Filariasis has not been known to exist here. Its introduction must be fairly recent, as none of the thirteen patients as yet show any pathologic changes. How it came here is uncertain. Several months ago a diagnosis of elephantiasis was made on a Jamaica negro who lived on the island about twenty years, but this diagnosis was made from characteristic enlargement of feet and legs. Several blood examinations had been negative. This man had been confined in the leper colony for five years with the diagnosis of leprosy. The examinations from the colony were all negative, as were those from Agat. Some fifty or sixty years ago this island was frequently visited by natives from the Caroline group who had removed to Saipan. An intelligent old native priest here says that some of these visitors had great enlargement of the legs, which from his description was evidently elephantiasis. About 1870 some Carolinos (about 400) were brought here to cultivate cotton. They lived together along the beach near Agaña. The last of these were deported in 1901. No one remembers seeing any of these with any lesions which resembled elephantiasis.

TWO AIDS IN MAKING BLOOD COUNTS

STERLING BUNNELL, M.D.
SAN FRANCISCO

1. The practitioner is sometimes in need of an immediate white count when at the bedside and far from a microscope. Here is a quick, satisfactory and easy method by which it can be done in the patient's room and the result will be the same as if the counting were done through a regular microscope.

Stopper
for blood
pipette.

Procedure.—Draw the blood into a pipette, dilute with acetic acid and place a drop in the Zeiss counting chamber in the usual way. Now hold the cover slip on the counting chamber with a rubber band. The chamber can then be held up to the light and the corpuscles will not slide across the field. The counting is done with a small pocket hand lens. A sixty-cent lens will do, but there are more powerful lenses on the market that are hardly larger than a pea and are even better. A single frosted electric bulb gives the best light but a lamp or most any single light will do. The knack of seeing the corpuscles and lines well enough to count them lies in holding the counting chamber and lens absolutely steadily in focus. This is easily done by grasping both with both hands so that the same fingers are in contact with both the lens and the counting chamber, thus preventing any tremor between them. Hold to the light and count. Occasionally a counting chamber is found on which the lines are not sufficiently distinct. The acetic solution should be filtered. It is easy then to tell which blood corpuscles from platelets. The reds cannot be counted in this way.

2. If the blood is gathered in pipettes and carried to the laboratory to be counted, the rubber band which is generally used to hold the blood in the pipettes, is often perforated by the point of the pipette and it is found with dismay that the blood has leaked out. Here is a device which prevents leakage, is quick of application and will fit in the case (see accompanying illustration).

Description.—In the bottom of a BB cartridge, a disk of rubber is cemented. The cartridge fits over the end of the pipette and by its rubber false bottom keeps the blood from escaping. A straight wire with a hook at one end is soldered to the cartridge. Another piece of wire twisted into a ring and also with a hook on the end is slipped over the other end of the pipette. An ordinary rubber band connects the two hooked ends of the wires and pulls them toward each other.

Procedure.—To apply the device fill the pipette, bend the rubber tube back on it, slip the wire ring over the tube end and pull down the cartridge, stretching the rubber band till it slips over the pointed end of the pipette as in the diagram. There is a short lever arm to the wire with the ring, by virtue of which the ring squeezes the rubber tube tightly and prevents the escape of blood.

240 Stockton Street.

Therapeutics

THERAPEUTIC VALUE OF MEDICAL INSPECTION OF SCHOOL CHILDREN

It is not the object of this article to discuss the advisability of the various municipal governments assuming more parental care of children, but to show that regular inspection of school children, whether by physicians appointed by the local government, or by private physicians selected by the families, is of enormous value in preventing the development of disease and of abnormalities in children from seven to fourteen years of age. It requires no discussion to assert that if a community compels a child of school age to go to school, the same community must protect that child from harm while obeying the community's mandates. In other words, the light, temperature, ventilation, air space per individual, and height and character of the chairs and desks on the one hand should be as near perfect as possible, and on the other hand a child suffering from contagion of any kind or one who has been exposed to contagion and is therefore likely to become infected, should not be allowed to enter the school building. This primarily means that the building committee of every schoolhouse should have in its membership one or more medical men capable of passing on the requirements of a healthful building. Secondly this presupposes the inspection of school children to prevent the spread of contagious diseases, and the establishment of such rules by the boards of health as is necessary to control a contagious disease and prevent its causing infection of others.

It also seems to require but little discussion that, when the authorities decide that a child should be compelled to use his eyes and ears systematically, it should know that these organs are in perfect condition, or made as near perfect as possible. In other words, the eyes and ears of school children should be inspected by some one competent to decide at least approximately whether the eyes or ears need scientific examination.

This still leaves open to discussion the advisability of the examination of children by medical inspectors appointed by the authorities, perhaps by the board of health, perhaps by the board of education, or by a com-

bined committee from both boards, once or twice a year to determine the physical condition of each school child. This would mean briefly an examination of the bones for curvatures and other deformities that could be corrected orthopedically, to examine the heart and lungs, to examine the teeth for cavities that should be filled and for decayed roots that should be removed, to decide whether or not the child has adenoids or obstructed nares which should receive attention, and especially to decide as to the general physical condition of the child, viz., as to his health or debility.

One cannot see how there can be any question of the preventive value of such an examination. Whether such examination should be made hastily by a public inspector, or more carefully by the family physician is open to discussion, but, certainly, if we are to have a robust nation each child should be medically inspected regularly, early in the fall, before he starts on his school year. It may be ideal, but it is good sense that a child should not be received as a pupil until he brings a certificate of apparent health and ability to withstand the confinement of school hours for the succeeding year.

It is likely to be argued that the nation as a whole is a pretty well nation, and that such inspections have never been necessary. Such an argument is footless and without careful consideration of the facts of advanced civilization. Most diseases are as fatal (except tuberculosis and diphtheria) as they have ever been. It is not because diseases are not better and more scientifically therapeutically handled, but because the nervous and circulatory strength of the individuals is very much less than it used to be. The nervous strain and tension of our lives, and especially the lives of our children, has enormously increased, and with all the advance in medical science it is just as difficult to bring a patient through a serious illness now as it ever was, perhaps more difficult. If there was no more medical knowledge than there was a hundred years ago, and if patients were treated therapeutically as they were a hundred years ago, most patients would die. Therefore, although medical knowledge and science have advanced, the difficulties of caring for patients who are ill have increased. Hence every possible method of prevention of disease and of the development of a disability, and of the growth of a tendency to disease should be utilized.

In the crowded city schools the whole aim seems to be to push the child mentally and take but little notice of him physically. The crowded condition of the lower grades is the ever present stimulus to push a child up to the next grade and to push him mentally until he is able to take part in the work of that grade. Consequently, the age of graduates of each grade is growing younger, and a child that is kept back from sickness becomes ashamed to enter the grade of his mental knowledge. All this is economically a mistake. Every physician will testify to the difficulty encountered with the parents and the child when he urges the removal of a child from school because he or she is debilitated. The whole family urges that the child may be kept at school until the end of the term, lest he lose his class, and they suggest all sorts of subterfuges to get around the desire of the physician to keep the child in the fresh air, away from school and away from all school work. The results of these school methods and the foolish pride of families are shown by the large number of growing boys and girls just before and just after puberty who are far below par physically. A certain percentage of these children never regain their physical strength.

To offset the methods that tend to physical debility, school gymnasiums and athletics have become distinctive of this age. An enormous amount of good is done by such athletic work, but also a lot of individual harm is done by severe athletic work being undertaken without medical supervision or jurisdiction. A child physically not strong competes with its fellows who are strong, and the result is, sooner or later, a physical wreck. Also, the rapid growing child, especially the boy, competes with the boy who has grown slowly and sturdily. The circulation of the rapidly growing boy, the heart especially, has not grown as rapidly as the rest of the boy, and it is constantly working at a disadvantage to overcome the extra work required of it, and if severe athletic work is added to its requirements it is insufficient and soon shows injury. In the case of girls, they may not do as severe athletic work, but they take injudicious athletic exercise, such as bicycling and tennis at periods during their establishment of puberty which means future trouble and possibly life long harm. Also these girls, who by the nature of the conditions and the stimulation of the physiologic secretions which they have during the establishment of puberty, are nervous, irritable, and neurotic. To Nature's disturbances are added excessive school work and the stimulation of competitive work, with the addition of the home pride causing them to take up the study of accomplishments, music and dancing, all during the period when the girl should be resting both mentally and physically. Added to this is the ever increasing tendency of the young growing girls and boys (and it is the girls who receive the most harm) to have evening social gatherings and dances, even to late into the night; in fact everything in the amusement line at this early age, which leaves to the girl or boy of nineteen or twenty but little that is new in amusements. This causes many of our girls to be neurotic and perhaps neurasthenic for the rest of their lives, much to the discomfort and disturbance and unhappiness of their families.

General medical inspection and the advice that is simply a corollary of such medical inspection would soon educate the public to the better care of its children. The advice of the individual physician without the general consensus of opinion is not nearly of as much value as it would be if general inspection was required.

It would be time well spent for every physician who has not read the book on "Medical Inspection of Schools," by Dr. Luther H. Gulick and Mr. Leonard P. Ayres, to read it. This book is published by the New York Charities Publication Committee.

At a recent meeting of the New Haven Medical Association, Dr. J. W. Seaver, of New Haven, president of the Chautauqua School of Physical Education and former medical director of the Yale Gymnasium, opened a discussion on the subject of medical inspection in public schools as follows:

There are few, if any, topics of more interest to the person who considers the welfare of the state than the training of the children, and for no one purpose do our citizens pay so large a tax, and no part of the general tax is paid so willingly. Of course there are a few people still permitted to reside in this part of the earth who think that for the public, the city, the town, to undertake to provide mental or any other form of training for the children within its borders is unjustifiable, but this coterie of antiquated intellectual maidens need not be considered as their objection is merely based on a natural timidity and a suggestion of socialism has thrown them into hysterics. Their condition is not as bad as it seems.

It must be assumed that the public school is here to remain and it behooves us to make the institution as helpful to the state as it can be made and to give it the thought and direction that so large an outlay in any direction should demand. This being a form of government where the initiative and control rests in the hands of the people, that is in our hands, it remains for us to make reasonable demands of our officers who are in charge of public organizations and to work for the formulation of these demands. I conceive this to be our purpose at this meeting. We are to create and crystalize sentiment, acting as citizens and as specialists in the subject of health.

What is a public school? It is an institution designed to give mental training to the children of certain ages at the expense of the people. Everybody being taxed for the support of the schools and the schools being utilized only by those who have children of suitable age, there must be some conceded benefit to the public from this expenditure to warrant the taxation. This has been estimated in terms of increased efficiency in the new prospective citizen and in some countries it is considered that the youth owes the state a certain definite service as a return, in part, of the expense that has been incurred on his account.

But while the manifest purpose of the school is to give mental training it has been found that this is only one phase of a complicated subject; that mentality of high order is not secured by mental gymnastics alone, but that it is a structure that is erected on a purely physical basis; that mental processes are strongest and most normal when they are accompanied by appropriate physical activities, and that a proper mental training is possible only when the body is kept in certain hygienic fitness by its functional activity.

No less an authority on education than G. Stanley Hall has said that for every thought there is a muscular response and that thought without previous sensory impressions is impossible.

If, then, we are to start with the idea of giving the best mental training to the boys and girls of our city we must coordinate the work of the teacher in the school room with that of the person who is trained to understand the correct hygienic environment of the pupil and to discover whether or not the pupils' receptive areas for sensory impressions are in normal condition, or in as near an approximation to that standard as is possible.

They must also be trained to appreciate the fact that a large number of the diseases from which humanity suffers are contagious or infectious in character, and understand the ways in which these disastrous diseases are prevented or restricted to the fewest possible under the general conditions under which we must live.

Up to the present time the only people who are thus trained are the doctors, and there is a burden of responsibility laid on them by the very fact of this training that we have not met by adequate activity and interest in the school problems of this city and state.

In the Winchester factory, near by, every part of the material is examined and every part is inspected and tested so that the finished product is as near perfect as the skill of man can produce, and the result is reliable service. Suppose the same persistent attempt to turn out the best possible product from our schools for the service of the world were to be established as a working principle in their management. Would not the quality of the product soon reimburse the slightly increased outlay? Obviously the same rules of administration will accomplish the same ends in either place.

What, then, would be the result of expert supervision of the school children and their housing and management during the school period of their lives?

In the first place, we would not expect the impossible from the pupil but we would first examine the child to see if the various organs were in satisfactory condition for functioning according to the demands of the school life. Any error that could be corrected would be reported to the parent and its importance stated. If it could not be remedied the teacher would be made cognizant of the difficulty under which the child worked and would be able to meet his needs in a fuller and more sympathetic manner.

But suppose the parent is indifferent to the welfare of the child and ignores the advice. The parent is rarely indifferent but he is often suspicious and negligent. Often he is poor and helpless. It is all well enough to say to a parent, your child needs the care of an ophthalmologist, or a rhinologist, or a dermatologist, but that will not produce the fee that must be paid, nor will it drive the self-respecting parent to the dispensary. Something ought to be done, and it would seem to me the part of good economy in the manufacture of citizens to have these children cared for by the city when the parent does not meet the responsibility. To turn out a bright mechanic, or merchant, or policeman, is better than to turn out a poor day laborer without ambition or confidence in himself to struggle vainly for the necessities of life and finally have to fall back on the public for the care that his old age demands and that is given alike to the unfortunate and the incapable.

The work done by Dr. Cronin in New York when he examined the pupils in one of the truant schools shows the needs of this hygienic inspection, for over ninety per cent. of those children needed medical care. He took 87 of these children who were suffering from adenoids or enlarged tonsils, or both, and had them treated in one day, and only three of them lost time in school and many of them advanced in scholarship to the extent of three grades during the remainder of the school year. Those poor unfortunate children had been made to compete with children not so handicapped, and the result had been that they had become discouraged and played truant, for they did not like the feeling of continued disgrace. When they were set free they made ample return for the care that was given them, and as citizens, who can compare their probable worth with the forlorn, discouraged, incompetent group of mouth breathers that would have been the output of that school had nothing radical been done.

The eye is the tool by which mainly information is obtained in school, and to know that this implement is fitted for its work is of the highest importance. To expect a child with poor vision to do good work in school is like asking a mechanic to turn out well finished work with dull tools. We convict ourselves of stupidity when we expect it.

As to the guard against contagious diseases, I shall say almost nothing, for others will show what can be done and what has been done. Every disease that is detected in its incipency is a saving of many lives and a greater amount of money than has ever been paid to any inspector. To neglect this side of the school life is the old penny wise and pound foolish policy. It costs no more energy to march in front than to drag along in the rear.

While a number of the cities have furnished valuable statistics obtained by medical inspection in schools, the following results obtained by Dr. W. Matthew Kenna, of New Haven, have not before been announced, and are well worth presentation. Besides the results of his inspection of 400 school children in a new and perfectly equipped school building, Kenna introduces his statistics with some thoughts worthy of consideration:

The necessity for the medical inspection of school children in this country as yet has not been generally accepted. In but one state in the union has there been taken legislative action requiring all the pupils in the state to undergo medical inspection. That is Massachusetts.

Including the cities and towns of that state there are only about 70 places in the United States which at the present time officially recognize the desirability of medical inspection and which make provision for such inspection to take place.

As in every other matter of this kind, there are arguments for and against the institution. Those who are most conservative, realizing the always present danger of paternalism of any kind make protests which at best are of compromising nature. They believe either that the health of the school children should essentially be dependent upon the acumen and solicitude of the respective parents or others in intimate touch with the home life; or that at most the pupils should be inspected only so far as to protect them from the invasion of contagious disease.

Many more enthusiastic citizens, however, are of the opinion that not only should children specifically, while in attendance at school, have some kind of medical supervision, and not only should they be guarded from the dangers of contagious disease, but in addition that they should be looked after in the matter of constitutional defects—defects capable of retarding development, both physical and mental.

This idea has its application not alone in an expression of sympathy and interest in the child himself, not merely in the general protection to the community, but in an economic sense as well. For it is practical to consider (if we care to look at it from a mercenary standpoint) that much money is being wasted yearly upon the education of children who are retarded by physical conditions which if corrected would render them more amenable to the standard required.

We may take three view-points of the relation of the child to the matter in hand.

1. Has the child, while in attendance at school, any need of medical supervision?
2. The relation of the child to the community at large.
3. The consideration of the child as an individual.

Let us take up the first proposition. If we allow that the school is merely an incidental to the scholar's home, that his attendance at school is simply an excerpt from his daily life and that the parental surveillance is only temporarily obscured—if we look at the matter from this standpoint alone, then it is reasonable to assume that the care of the child's physical condition should devolve on the parents, and that there is no need for school medical inspection.

But it is easily recognized that there is a relation between school children and the community at large and that as carriers of contagious diseases they are a constant menace to that community.

Addressing ourselves to this, the second viewpoint, it is obvious that there is good reason for attempting to prevent as well as can be the dissemination of disease, both for the scholars' sake and for that of those with whom they may come in contact. And so if we grant the advantage to be gained from the mutual protection of the child and the community from contagious diseases it is not a far cry to the consideration of the third view-point, taking the child as an individual, and bearing in mind his possible constitutional physical defects.

How about the child himself? Is he entitled to supervision of a medical nature that may uncover bodily defects which otherwise might not be recognized and which might have a restraining effect on his fullest development? If we answer yes and accept this viewpoint then there is the fullest justification for a thorough and complete medical inspection in the school. Take, for instance, the matter of the common adenoids. It is undoubtedly true that many children suffering from these growths are never taken to a physician for treatment. This may be due to either ignorance or carelessness on the part of the parents. At any rate, there is lack of initiative on somebody's part and the children go through several years of their lives severely and unjustly handicapped.

Assuming that the tendency of such defects is to disappear as the child grows older, yet we must reflect how much better off he might have been had the lesion been eliminated. There is plenty of precedent for the adoption of a thorough medical inspection of our own schools. Several European countries as well as Japan have at the present time inspection which is national in its scope. There the inspection is rigid to an extreme degree, and there are many evidences of the benefit to be derived from the thorough examination of the school pupils. The very fact that these countries, like Germany, England, and Japan, are of the so-called military type throws out the hint that they are looking to the future with a practical as well as sentimental eye.

Medical inspection as related merely to the prevention of contagious and parasitic diseases has its value unquestionably. But the ideal inspection would be that which not only concerned itself with those diseases, but would also turn its investigating attention to the physical defects barring the child's school progress.

Here in New Haven, as you know, the medical inspection of schools relates more especially to the detection of contagious

and parasitic diseases and the elimination of vermin. That some good has resulted may be emphasized by the fact that since the inception of the inspection, impetigo, which was formerly very prevalent among the children, has been practically stamped out.

Medical inspection to be of greatest value must be more or less of a cooperative nature. It involves the working together of the visiting nurse, the teacher, the parent, the family physician and the medical inspector. Without such cooperation there is apt to be a break in the link and no ultimate results follow. Simply to find out that a child has some physical defect and to do nothing to alleviate it, accomplishes little. The essential point is to have treatment instituted, and this will not be effected unless some kind of pressure is brought to bear on the parents and their eyes opened to the necessity for such treatment. Under these conditions thorough medical inspection of the pupils will have been worth while.

Recently (spring of 1910) I made an examination of 400 school children taken indiscriminately. The results of the examination are shown in the accompanying table. An attempt was made to make three degrees of severity where lesions were apparent, and "A" denotes that a defect was present, but did not require treatment; "B" denotes that treatment was advisable; and "C" that treatment was imperative. The physical condition of the children was divided into three groups, viz., "good," "fair," and "poor." The examination followed was practically that which is required in the medical inspection of the pupils of the New York City schools.

TABLE OF RESULTS OF EXAMINATION OF SCHOOL CHILDREN

	Good.	Fair.	Poor.	Total.
Apparent physical condition.....	171	104	125	400
	A	B	C	Total.

Formaldehyd Solution for Treatment of Appendix Stump.—Dr. A. Merrill Miller, Danville, Ill., writes: Whatever may be the ideal method of "treating the stump" of an appendix, well-informed and conscientious operators still entertain opinions widely divergent. Each group of men bases the treatment on their own, or perhaps a leading operator's, personal experience. The fact that equally good statistics, in use, are shown from the different methods, may make a suggestion in this matter appear superfluous. The septic muco-sa is usually cut away, treated with phenol and alcohol, or inverted. Perhaps a combination of all three methods is used. Because the use of phenol is attended by necrosis, it seems that little is to be gained from this practice. Then, there is the additional loss of time in the application of alcohol. To overcome the objection of a chemical necrosis in the base—an ideal place, it seems, for the proximate intestinal bacteria to multiply—I have adopted the practice of mopping the stump with 16 per cent. formaldehyd solution. This favors mummification of the tissues, destroys the mucous membrane, and may tend to limit small hemorrhages if the stump is not tied. Certainly a dry mummified stump is a less desirable place for bacterial growth than the raw, sloughing surface following the phenol application. Especially is this true if the stump is not inverted, or covered. The likelihood of adhesions from such tissues is less than by the use of any other method with which I am familiar. The amount of time—thirty seconds—consumed by this simple procedure is no reasonable objection to its use.

THE IMPORTANCE OF THE TYPHOID-CARRIER

Evidence is accumulating that the share of the typhoid-carrier in disseminating infection has not been overestimated. The intensive study of typhoid fever by German investigators in the Rhine provinces has been frequently referred to in *THE JOURNAL* and has definitively established the fact that in the rural districts of Alsace-Lorraine and the Palatinate the major part is played by contact infection. Much more general conclusions may now, however, be drawn. It is safe to say that a large part, perhaps the largest part, of the "residual" or "prosodemic" typhoid observed in a community possessing a pure water-supply is to be attributed to contact infection. Even milk-borne epidemics are being traced in a surprisingly large number of cases to contamination of the milk by bacillus-carriers at the time of collection or in the course of distribution. The facility with which typhoid bacilli multiply in milk naturally renders this foodstuff a relatively common vehicle of disease, but the way contamination of the milk occurs is in many cases precisely similar to the mode of contamination of any other article of diet. There can, furthermore, be no doubt that a part of the danger lurking in open privies is due to their use by unrecognized carriers, using this term in the broad sense. Well-defined cases of typhoid are, of course, responsible for some scattering of infection of this character, but much also must be laid at the door of the "walking" patients, the healthy carriers and the obscure cases. To these are now to be added those individuals who, as shown by Conradi, Mayer and Drigalski, may be discharging typhoid bacilli in the stools or urine for as long as eight, eleven, or even twenty-five days before the malady has become clinically manifest. The recent discovery that children suffer not infrequently from a mild, ambulant, unrecognized form of typhoid¹ is also important in this connection. Several epidemics in western Germany have been traced to clinically unrecognized cases of this character. Altogether the living

distributors of typhoid bacilli make up a formidable array.

It does not seem worth while to discuss the singular stand taken by Delorme in his recent communication to the French Academy of Medicine.² No one cognizant of the evidence can maintain to-day that drinking-water is, in all places, the chief vehicle of typhoid or that contact infection is rare and exceptional. The success of the German campaign against rural typhoid, already referred to, is a demonstration of the efficacy of measures undertaken to prevent spread by contact. The number of cases in the infected district, which in 1904 was 3,487, was reduced in five years, by the measures against contacts and carriers, to 1,648. It is equally idle to dispute over the relative share at the present day of water and other sources of infection. Water, especially in this country and in France, is too commonly the means of communicating typhoid fever. That this is so should not lead us to overlook or to minimize other and equally well-known possibilities of communication.

Perhaps one reason why typhoid fever does not diminish more rapidly when cities substitute a pure water-supply for a polluted one is that in such cases there is a legacy of carriers handed on from the days when water-borne disease prevailed excessively. The carriers produced by years of infected water-supply do not disappear at once, but linger on and generate new foci long after the original trouble has been removed. Every city that continues to tolerate a polluted water-supply is not only suffering present injury, but also is storing up for itself future trouble, by accumulating a crop of carriers which may continue for long years to plague it.

One thing at least is plain, that the problem of residual or prosodemic typhoid is largely—perhaps mainly—the problem of the carrier. Difficult and often impossible to track to his lair, still more difficult when cornered to deal with fairly as an individual and rigorously as a public health danger, the carrier is coming to be more and more an object of serious concern in the fight against typhoid fever. A hopeful feature of the situation is that the effect of preventive measures is cumulative. Progress in the purification of water-supplies will in the long run decrease the number of carriers. The discovery and control of a single carrier, particularly in occupations such as the purveying of milk which involve special danger, may be the means of preventing the formation of many new carriers. It may be that the gradual elimination of the carrier is one reason for the steady diminution in the amount of typhoid fever observed during the last few decades, even in communities like Munich or The Hague, which have long been blessed with uncontaminated water. At all events, the carrier cannot be lost sight of in any attempt to control typhoid fever at its source.

FARMERS' BULLETINS

One of the objections urged against the establishment of a national Department of Public Health has been that such work does not properly belong to the federal government. As a matter of fact, the national government is already carrying on exactly such work as would be developed by such a department, but it is being done under the authority of one or more of the existing departments. As has been already pointed out in the hearings before the house and senate committees, what is desired in the establishment of a specific health bureau or department of the national government is not so much the inauguration of any new work, as the extension, correlation and systematization of work already being done in various departments. This is well illustrated in a circular recently issued by the Division of Publications of the United States Department of Agriculture, giving a list of the "Farmers' Bulletins" issued by the department. In past years a large number of pamphlets containing valuable information by experts has been issued by the Department of Agriculture, being inaugurated originally to convey to the farmer the necessary information regarding animal and vegetable pests, etc. This work has since been expanded so as to include pamphlets on almost every subject that relates to the farmer's physical or material well-being. Whatever improves the health of the farmer and his family would also improve the health of the citizens who were not farmers; yet, as the Department of Agriculture has authority to issue bulletins to farmers but not to the citizens, these pamphlets are sent out as "Farmers' Bulletins." A glance at a few of the titles is interesting. No. 34, "Meats, Composition and Cooking;" No. 85, "Fish as Food;" No. 93, "Sugar as Food;" No. 121, "Beans, Peas and Other Legumes as Food;" No. 128, "Eggs and Their Uses as Food;" No. 182, "Poultry as Food;" No. 249, "Cereal and Breakfast Foods;" No. 375, "Care of Food in the Home;" No. 377, "Harmfulness of Headache Mixtures;" No. 391, "Economic Use of Meat in the Home," etc.

It would be difficult to show why the national government should be any more interested in the food of the farmer than in the food of any other citizen, or why pamphlets such as those cited above, if good for the farmer, are not good for all other citizens. It is also difficult to see how the publication and distribution of such pamphlets in any way interferes with "personal liberty" or "forces one to accept medical services which he does not desire." In fact, the effect of such publications would seem to be to diminish the need for medical services of any kind.

A number of the pamphlets are worth noting as showing the interest of the government in diseases of plants and animals. Some of these are: No. 28, "Weeds, and How to Kill Them;" No. 30, "Grape Disease on the Pacific Coast;" No. 82, "The Culture of Tobacco;" No. 91, "Potato Diseases and Treatment;" No. 99, "Insect

Enemies of Shade-Trees;" No. 110, "Rice-Culture in the United States;" No. 113, "The Apple, and How to Grow It;" No. 120, "Insects Affecting Tobacco;" No. 127, "Important Insecticides;" No. 152, "Scabies of Cattle;" No. 155, "How Insects Affect Health in Rural Districts;" No. 177, "Squab Raising;" No. 205, "Pig Management;" No. 379, "Hog Cholera."

The independence and personal freedom of the farmer does not seem to have been invaded by the publication and distribution of these pamphlets, neither has their preparation been controlled by an "agricultural trust." If similar publications on child culture instead of asparagus culture, or on infant management instead of pig management, were prepared by a properly organized health department, would the liberty of the people be endangered? Why should the government prepare and distribute pamphlets on "Grape Diseases on the Pacific Coast" and yet have no information for its citizens on water diseases in the Mississippi Valley? The series of farmers' bulletins prepared by the Department of Agriculture is most praiseworthy and valuable, but the government should abandon the subterfuge of authorizing such life-saving work under the name of "Farmers' Bulletins" because it has a Department of Agriculture and not a Department of Public Health, and should establish instead a department adequately equipped to advise all citizens regarding matters affecting their health and well-being.

EHRlich's NEW REMEDY FOR SYPHILIS

A new remedy for syphilis, recently announced by Ehrlich and Hata, under the somewhat mysterious name "606," seems to have been received in Continental medical circles with unwonted enthusiasm. This is shown by reports already published in our Berlin letter and the communications of our Budapest and Berlin correspondents in this issue and by the abstract in our Miscellany Department. The new product is the result of a long series of experiments carefully planned with the end in view of finding a remedy which will destroy spirochetes, particularly those of syphilis.

It is claimed to be an example of the complete destruction of the pathogenic agents of a disease by a medicinal product acting within the organism. It consists of a compound of arsenic allied to arsenilic acid and possessing the composition indicated by the name dioxo-diaminoarsenobenzol. Apparently it was selected out of a large number of similar compounds by experimental trials, and only after numerous successes on apes and other animals was tried on man. The results as described by Weichselmann,¹ Neisser,² and others, impress one as being little short of marvelous. The startling statement is made that spirochetes begin to disappear from chancres and condylomata in a few hours and

1. See page 617, this issue.

2. Berlin. klin. Wchnschr., July 4, 1910.

3. Deutsch. med. Wchnschr., June 30, 1910.

are completely gone in from twenty-four to forty-eight hours. Syphilitic lesions such as rupia, papules, ulcers, etc., we are told, heal with remarkable rapidity.

Considering the reputation and standing of the men who make the announcement, it seems possible that an agent more active and more powerful than mercury is about to be placed in the hands of the profession to be used against one of the most dreadful diseases from which humanity suffers. Considering its character it might be supposed that the remedy would be a dangerous one and yet it may not be. Arsenic is such a potent drug, however, that involuntarily the cautious think of the old saying: "Timeo Danaos et dona ferentes"—"I fear the Greeks even when they are bringing gifts."

The remedy is not yet on the market and probably will not be until the present uncertainties regarding dosage, mode of administration, etc., are cleared up by further investigation in hospitals. Meanwhile, it would be well to receive the various reports with due conservatism, bearing in mind the natural tendency to optimism on the part of those conducting such important investigations which seem so full of promise.

Current Comment

THE DRAMA OF SANITATION

A moving picture playlet illustrative of the dangers of impure milk is reported in preparation. Camera men have been snapping unhygienic farms to this end. The first scene represents the son of an old-fashioned, bacteria-despising farmer returning to the old homestead with his wife and little boy. The filthy cow-barns, the open pails of milk receptive to dust and flies are depicted with unsparing realism. The son, who has imbibed wholesome education in hygiene, protests passionately against the old order, but in vain, whereupon the young couple pack their trunks, leaving the old farmer in tears over the deserted baby-carriage of his grandson. The rural scene is then changed to an urban one. The formerly happy home of the old farmer's son is grievously distressed because of the baby's illness. The family doctor shakes his head and, pointing to the milk-bottle, indicates plainly the cause of the illness. The grief-stricken son writes to his father (letter flashed on the screen), who comes in haste; and finds, to his great anguish, that the bad milk has come from his own farm. Emotional climax! The play, however, ends happily; the farmer's barns are shown repainted and wonderfully refurbished, the cows washed, the dairymen in white suits presiding over now impeccably sanitary functions. The little patient? Evidently the family doctor has done something more than shake his head, for, miraculously restored to health, the little boy, held by his repentant grandparents, watches with interest the hygienic proceedings. Such a representation might amuse the highly intellectual, but it should certainly be of value in reaching that part of the community which would

take it seriously and which would be impressed by the scientific lessons embodied in it. Of well-proven value is a similar moving picture representation of "the filthy fly," which is being shown in our cities under the auspices of the American Civic Association.

FILTH AND TYPHOID

There is usually more than one aspect to a disputed question. This is true even of the celebrated Budd-Murchison typhoid controversy, which is so often declared to have ended in the complete overthrow of Murchison, horse, foot, and dragoons. No one, of course, believes to-day Murchison's hypothesis that the typhoid virus is generated spontaneously or *de novo* in decomposing organic matter, but it is clear that his observations on the connection between typhoid fever and filth were in themselves quite sound. The modern discovery of the existence of healthy typhoid bacillus-carriers, who have never had the disease themselves, explains why it is sometimes impossible to trace every case of typhoid to an immediately preexisting case. Since the hunting down of all carriers is practically impossible, it is necessary to deal with fecal accumulations in general as if they were definitely infectious. The open privy or earth-closet in city or country must be regarded always as potentially dangerous. We should not forget that accumulations of filth of any character tempt to further additions. It is a waste of time to try to prove filth innocent. If we assume it to be guilty from the outset, we are taking no unnecessary chances.

IT PAYS

We learn from a Denver correspondent that one of the vice-presidents of the "National League for Medical Freedom" was in that city recently organizing a "branch" of this latest enterprise of the "patent medicine" interests. This gentleman, who when not more profitably engaged runs a small country newspaper, is going about the country organizing forces—as though they were not already organized!—to fight the wicked "doctors' trust." Our correspondent says that while in Denver the "organizer" engaged an expensive suite in the most expensive hotel in the city! Verily the lines of this "trust-buster" have fallen in pleasant places.

RATTLESNAKE BITE

Every little while some one makes the statement that the rattlesnake bite is not fatal. This time it seems to have been announced from a medical society in Colorado, and a mud poultice is said to be a remedy sufficient to prevent evil effects. It is probable that the small rattlesnake of the western states, the so-called massasauga, is comparatively innocuous; that is, its bite is not necessarily fatal. But anyone who will make the assertion that the bite of one of the larger species is not serious enough to be dreaded goes against the experience of the medical profession, many of whom can give instances of fatalities thus caused, and that; too, in spite of treatment.

A NEW FORM OF HUMAN TRYPANOSOMIASIS

Dr. Carlos Chagas, a physician of Brazil, is reported to have discovered a new form of human trypanosomiasis. It is caused by a trypanosome which he has named *Schizotrypanum cruzi*. The parasite was discovered by him in the hind gut of a large biting bug, locally known as "barbeiro," which infests in large numbers the hovels of the poorer working class, remaining hidden during the day and issuing forth in the dark. This bug belongs to the *Hemiptera heteroptera*, family *Reduviidae*, genus *Conorrhinus*, is more than an inch in length and bites its human victim chiefly on the face. The course of the disease seems as yet imperfectly known. Children especially are attacked and the illness is characterized by extreme anemia, edema, general or partial enlargement of lymph nodes, thyroid and spleen, functional disturbances, especially of the nervous system, and frequent imbecility. The mortality appears to be great, death being often attributed to convulsions. The disease closely resembles ankylostomiasis, but is easily differentiated from this by an examination of the feces. The disease also differs from the African trypanosomiasis in that somnolence as a symptom is never present. A detailed report is contained in the sixteenth *Bulletin of the Sleeping-Sickness Bureau*.¹

Medical News

ILLINOIS

Infant Mortality at Springfield.—The monthly report of Dr. George T. Palmer, health officer at Springfield, shows that during the month of July there was an increase in the death rate of infants under two years of age of about 35 per cent.

New Hospitals.—As a first step toward the establishment of a much-needed hospital at Sterling, the city council recently appropriated \$500 to be used for hospital purposes. The cornerstone of the new Monmouth hospital was laid August 2. J. B. Brown delivered the address.

Personal.—Dr. William M. Johnson, Johnsonville, nestor of the medical profession of Wayne County, has been elected president of the county medical society. Dr. Johnson is 81 years old.—Dr. Will H. Perry has been appointed pension examining surgeon at Sterling to fill the vacancy caused by the death of Dr. Alexander C. Smith.

Advocates Hygienic Experiment Station.—At the meeting of the Summer School at Havana July 26, Dean E. J. Townsend of the University of Illinois, in an address on "Science and Public Service," suggested a plan for the establishment of an experiment station of sanitary sciences and preventive medicine, to work alongside of the agriculture and engineering experiment stations of Illinois. He declared also that education of the public as to the sources of danger is equally important. He called attention to Chicago as a good illustration of what a scientific and efficient leadership in sanitation can accomplish, pointing out that Chicago has now the lowest death rate of any American city of more than 350,000. His plan for an experiment station included the following features: That it should supplement the work done by the state and municipal boards of health; that a laboratory of physiologic chemistry should be maintained, in which questions of human nutrition could be studied; for the conduct of a bacteriologic laboratory; for the creation of a laboratory of sanitary science in which problems arising from water supplies, sewage disposal, etc., and their relations to public health should be investigated; for the establishment of a

department of medical research; not for teaching, but for inquiry into the cause and prevention as well as cure of such diseases as have not yielded to medical treatment.

Chicago

The Typhoid Campaign.—Dr. Leslie L. Lumsden, who is conducting the campaign against typhoid fever in the city, requests a meeting of physicians to discuss the situation. The medical societies of the city have no regular meetings during the summer and it is desired that special meetings be called.

The Weather and Mortality.—According to the bulletin of the health department July had a 6 per cent. higher death rate than the average of that month for the last ten years, and 23 per cent. higher than for July, 1909. The weather during July averaged 3.6 degrees above the normal of the month. It was the hottest July in nine years, and the average temperature was exceeded only once in thirty-nine years. While the death rate in infants was 42 during July this year, it was lower than the death rate in 1897 when it was 71 per 10,000 population, and lower than in 1901 when the death rate was 44, making the rate 45 per cent. lower than in 1897 and 5 per cent. lower than in 1901, in both of which years the temperature, though high, was not so high as in July of this year.

Plans Death to Flies.—John J. Davis, assistant state entomologist, in his experiments in the destruction of flies and fly larvæ, has found that a solution of iron sulphate is probably the best and cheapest agent. He advocates that experiments with this material in preventing the multiplication of flies should be conducted by the health authorities of Chicago in certain limited districts, and believes that a noticeable effect will be produced on the prevalence of intestinal diseases in the experimental area. In an experiment at Dunning a year ago, Dr. Pollock kept one ward screened from flies during the season. In that ward there was one case of intestinal trouble which lasted three days. In the next ward, which was not screened, there were seven cases in the same length of time and every one of these cases lasted from three to seven weeks.—A fly hatchery has been added to the city laboratory and Dr. John W. Viers is conducting experiments in the destruction of fly larvæ. Flies are being hatched in wire cages. It has been found that a phenol solution sprinkled on hatching grounds, on garbage and on manure will kill them.

Discuss Dumping Refuse in the Lake.—The question of the cooperation of the government in enforcing the law which prohibits dumping refuse in the lake within the eight-mile limit, recently referred to the chief engineer of the United States Army, has been answered in a communication from General Bixby, chief engineer, in which he says that the city of Chicago must mark the zone within which dumping is illegal by buoys and must provide inspectors to see that the law is enforced, as no money has been appropriated by Congress to enable the War Department to assist in the matter.

INDIANA

Personal.—Dr. Harrison Gabel, a physician at Centerville, was seriously wounded by being shot by a Civil War veteran, who is said to suffer from illusions.—Dr. William F. King, Columbia City, has been selected by the State Board of Health for special field duty in the study of epidemics or marked increase in any disease in any part of the state. On each mission, he will take exhibits prepared by the State Board, showing methods of combating the disease.—Dr. Clay A. Ball, Muncie, has been appointed deputy county health officer, to succeed Dr. Howard Drumm.—Dr. Jesse F. Davidson, Crawfordsville, supreme medical examiner of the Tribe of Ben-Hur, has been selected as assistant to succeed Dr. Royal H. Gerard, chief of the order. Dr. Alexander P. Fitch, formerly of Lebanon, has succeeded Dr. Davidson.—Dr. Adoniram J. Banker, Columbus, is critically ill.—Dr. Henry O. Bruggeman, Fort Wayne, who is now in Germany for study, has been elected president of the Anglo-American Medical Society in Berlin.—Dr. George H. Pendleton, physician at the Marion County Workhouse, has resigned, and Dr. Thomas Sullivan has been appointed to the position.—Dr. Samuel E. Smith, superintendent of the Insane Hospital at Richmond, has been appointed on a committee of the American Medical Association to welcome the International Prison Congress which meets in Washington, D. C., in October.—Dr. Hugh J.

1. Chagas' preliminary report was published in the *Brazil Medico*, May 1, 1910.

Downey, Middletown, N. Y., has been appointed resident physician at the Indiana Home Hospital, Terre Haute.

MARYLAND

New Hospital for Hagerstown.—Hagerstown is to have a hospital to cost \$60,000. It will be built under the direction of Dr. Henry M. Hurd, of Baltimore. It will be of brick and stone with concrete foundation.

Personal.—Dr. Richard S. Hill, Prince George's County, has been elected director of the Department of Farmers' Institutes of the Maryland Agricultural College and Experiment Station. Dr. Hill is a successful farmer and tobacco planter and has been special state tobacco agent for the last four years. He is also president of the Southern Maryland Agricultural Fair Association. The law requires that the incumbent of the office shall be a practical farmer.—Dr. Arlington G. Horine has been reelected mayor of Brunswick.—Dr. Ira J. McCurdy, health officer of Frederick, urges an incinerating and reducing plant for disposal of garbage and suggests a cemetery for animals.—Dr. Pedro de Figamiere, Zion, Cecil County, has been appointed to a government position in Alaska.—Dr. Thomas Z. Offutt, Granite, 80 years old, is recovering from a severe attack of pneumonia. He has practiced fifty years and was a surgeon in the Confederate Army.

Baltimore

Typhoid Fever.—Fifty cases of typhoid fever were reported for the week ending July 30, double the number of last year; 77 cases were reported for the week ending August 6, with four deaths.

Personal.—Dr. G. M. Linthicum, ex-president of the state society, has entered the Maryland General Hospital for treatment for supposed typhoid fever.—Dr. Summerfield B. Bond sailed for a trip to Norway and Sweden, July 30.—Dr. J. George Schmetzer has been motoring in England and Scotland.

Accidents During July.—During July twenty-three persons were injured by falling objects, as milk bottles, etc.; forty-six persons were bitten by dogs; thirty-three were burned; twenty-five were overcome by heat; ten were accidentally shot; four took poison by mistake. The total of accidents was four hundred and eight.

More Provision for Infectious Diseases.—Dr. James Bosley, Commissioner of Health, says the provisions for the treatment of infectious diseases at the public hospital (Sydenham) are entirely inadequate. The ordinance founding it provided for the treatment of diphtheria, measles, scarlet fever and chicken pox. But the money appropriated was sufficient only for one ward. That has been divided into two sections, in which cases of diphtheria and scarlet fever are treated. Four wards are needed and it is proposed to ask the board of estimates for \$60,000 to erect two new wards next year.

MINNESOTA

Free Dispensary for Duluth.—Efforts are being made at Duluth to provide a free dispensary, there being no such institution in the city at present.

No Appropriation for Tuberculosis.—The county commissioners at St. Paul are opposed to an appropriation of \$91,000 asked for the support of a tuberculosis ward at the City and County Hospital.

Personal.—Dr. Clara M. Hayden, Clarinda, Iowa, has been made women's physician at the state hospital to take the place of Dr. Olive Thorne, resigned.—Dr. Carl B. Teisberg, St. Paul, has been appointed assistant physician at the county hospital.—Dr. Gustavus T. Newman, New London, has been appointed superintendent of the new hospital at the Minnesota State Prison.—Dr. William H. Rowe, mayor of St. James, has been appointed by the governor surgeon-general of the state militia to succeed Dr. Alexander J. Stone.

Southern Minnesota Meeting.—The eighteenth annual meeting of the Southern Minnesota Medical Association was held at Winona August 4. Important action looking to consolidation of the Southern Minnesota Medical Association with the Minnesota Valley Medical Association was taken. Dr. William J. Mayo, among others, favored the plan of union and a committee was appointed to confer with a like committee from the other association on the matter. The following officers were elected: President, Dr. Theodore L. Hatch, Owatonna;

vice-presidents, Drs. Hugh F. McCaughey, Winona, and John E. Crewe, Rochester; and secretary-treasurer, Dr. William T. Adams, Elgin.

MISSOURI

Hospital Interns Resign.—Within the last month three of the interns at the City Hospital, St. Louis, have resigned on account of dissatisfaction with the food, their sleeping quarters and their personal treatment by the management of the hospital.

Circulating Medical Library.—The field covered by the library of the University of Missouri is to be extended over the state. On request the state librarian will furnish county medical societies with books for local circulating libraries. The library has recently added to the list of reference books several hundred books and periodicals on medicine.

New Hospital.—Mrs. Jane Chinn has donated \$100,000 for the erection and maintenance of a hospital at Webb City. The Jane Chinn Hospital Association has been incorporated, and a building committee has been organized with Dr. Charles E. McBride at its head. He is also president of the board of trustees. The building and equipment will cost \$40,000.

Changes in Washington University.—The 1910 catalogue of the Medical Department of Washington University shows that radical changes have been made in the faculty. Ten prominent St. Louis physicians connected with the school for many years have withdrawn. Dr. George Dock, who has recently come from Tulane University, New Orleans, to Washington University, has been made dean of the medical faculty. Dr. Horatio N. Spencer has resigned.

Personal.—Dr. William G. Rowe has resigned as county physician at Blue Springs.—Dr. Arthur A. Hobbs, Kansas City, has been appointed superintendent of the county hospital. He will also act as county physician.—Drs. Oscar H. Elbrecht and Willard Bartlett have been appointed surgeons of the consulting staff of the City Hospital, St. Louis.—Dr. William P. Patterson, Springfield, has been appointed chairman of the committee to arrange for medical examinations of the schools of St. Louis, Kansas City and Joplin.

Recommendations by Health Commissioner.—Dr. Walter S. Wheeler, health commissioner of Kansas City, in his annual report complains of physicians who fail to report reportable diseases and recommends that they be fined for violating the ordinance. He recommends an incineration plant for the disposal of the city garbage and urges more thorough milk inspection and a thorough campaign of education of the public in regard to tuberculosis. He also finds that there are five mentally defective children in every hundred of the 25,000 pupils enrolled in the city. He recommends that a separate school be provided for such defective children.

MONTANA

Nurses' Home.—A nurses' home to cost \$15,000 is in course of erection at the Montana Deaconess Hospital, Great Falls. Three nurses were graduated from the training school of the hospital in June.

Personal.—Dr. John T. Foley has been chosen assistant county health officer at Lewiston to act in the absence of Dr. Willard A. Long, who is in Europe.—Dr. Eugene G. Campana has been made city physician at Butte.—Dr. Francis M. Flinn has been appointed surgeon, with rank of captain, of the battalion of the national guard, composed of one company at Libby and two at Kalispell.—At the annual meeting of the Antituberculosis League, Dr. Sisson of Butte was elected secretary; Dr. Atwood, Helena, treasurer, and Dr. E. M. Hunter, Livingston, chairman of the executive committee.

NEW JERSEY

Personal.—Dr. D. W. Blake, Jr., was elected medical inspector by the Gloucester Board of Education.

Infant Paralysis at Burlington.—Six cases of infant paralysis are reported in Burlington. None of them has so far resulted fatally, but all of the victims are believed to be incurably crippled.

Shower Baths.—The board of works of Newark, following an order of the board of health to close swimming pools in the public baths because they are considered unsanitary, have

directed that shower baths be installed without further delay, and all public baths will be thus equipped.

Millville Fears Smallpox.—The State Board of Health held a meeting at Millville August 4 to take steps to check an epidemic said to threaten the town. For the last two months, it is declared, there has been a score of smallpox cases wrongly diagnosed as chickenpox. Charges that physicians have been lax will be probed by the state board. A dozen homes have been placed under quarantine and wholesale vaccination has been begun.

Advocates Public School Clinic.—Dr. George J. Holmes, medical supervisor of the Newark Public School, urges the establishment of a public school clinic. This, if centrally located, would enable public school physicians to keep in closer touch with cases coming under their care and would result in a saving of time. Special classes for defective children and for the blind, deaf and dumb were authorized by the Board of Education.

State Board of Health Report.—The report of the State Board of Health for July shows that the increase of deaths from infantile diarrhea during the month is larger than for any corresponding period during the past five years, which is in line with the report from other states, amounting to 345 deaths as compared with the next highest figures, 202, for 1908. Typhoid fever deaths for July numbered 37, the average per month for the previous twelve months being 25. Six hundred and fifty-three specimens of milk were examined by the state laboratory, 609 of which were found to be above standard and only 44 below.

Decision Regarding Sewage.—The supreme court, in an opinion handed down July 20, holds that the Borough of Garwood may empty the effluent of its sewage disposal plant into the Rahway River. This action of the Borough of Garwood was approved by the state board of health under the provision of the law which gives state boards the same powers as were formerly held by the state sewage commission. In holding that the law is constitutional Justice Parker says that "the effect of the legislation is to make the state board of health *ex officio* the state sewage commission, as far as the sewage disposal plant and these proceedings are concerned."

NEW YORK

Medical Library for Schenectady.—A medical library consisting of 1,000 volumes has been loaned by the State Medical Association library at Brooklyn, to the medical society at Schenectady. It will be located in the public library building.

State Exhibit.—The state health department and the State Charities Aid Association have again arranged a schedule for the large state tuberculosis exhibit which will go first to Saratoga in September.

Temporary Tuberculosis Hospital.—The board of county supervisors at Rochester has established a tent colony on the county farm in Brighton for the care of tuberculosis patients from the County Hospital, on recommendation of the Rochester Public Health Association.

New President. New York State Society.—By the death of Dr. Charles Jewett August 6, Dr. Charles Storer, vice-president, succeeds to the presidency of the Medical Society of the State of New York. He is a prominent practitioner of Amsterdam and physician to the City and St. Mary's Hospitals.

Personal.—Dr. Isham G. Harris of Poughkeepsie has been appointed superintendent of the new Mohansic State Hospital near Peekskill.—Dr. Edward H. Fiske, Brooklyn, was operated on at Oswego for appendicitis, while away on his summer vacation.—Dr. W. O. Smith has been made health officer at Falconer.

New Hospital for Children.—At a meeting of the fraternal organization committee, Dr. Montgomery E. Leary, supervising director of the Rochester Public Health Association, outlined his plan for establishing a children's hospital by all of the fraternal organizations of the city, and a committee was appointed to report later on the feasibility of the project.

New York City

Typhoid Fever.—For the week ending July 23 there were 59 cases of typhoid fever with 6 deaths; for the week ending July 30 there were 91 cases with 17 deaths.

Deadly Record for July.—During the month of July there were 18 persons killed and 153 injured on the streets of this city; of these 13 were children under 12 years of age. During the first six months of the year there were 93 killed and 522 injured.

To Enlarge Tuberculosis Clinic.—Plans have been filed for an addition to the tuberculosis clinic on the roof of the Vanderbilt Clinic at Amsterdam Avenue and Sixtieth Street. The addition will be a one-story structure. The laboratory of the clinic will also be enlarged at a cost of about \$6,000.

Personal.—Drs. J. Morgan Howe, Alexander Lambert and W. K. Draper have sailed for Europe.—Dr. F. M. Shook, Medical Corps, U. S. Navy, has been detailed to conduct lecture and laboratory courses on tropical medicine at the New York Post-Graduate Medical School during the months of August and September.

Death Rate Continues High.—The death rate for the week ending July 23 was 18.80 per 1,000 population, while the rate for the corresponding week of last year was 16.96. The death rate in institutions was again higher, there being 608 deaths compared with 485 for last year. Dr. Lederle has appointed a committee to investigate the reasons for the high death rate in both public and private institutions.

Pure Food Laws Made Ineffective.—The ineffectiveness of the pure food laws is being attributed to the failure of the courts to impose as severe penalties as are warranted. There is no lack of industry on the part of those charged with the enforcement of the law in securing conviction for the offenders but the fines imposed are in many cases so trivial as to have no effect in securing obedience to the laws. For instance, in a sale of soothing syrup, guaranteed to be perfectly harmless but found to contain morphin, \$10 was imposed; sales of four headache remedies, guaranteed harmless but found to contain acetanilid, resulted in fines of but \$15 each; a fine of only \$5 was imposed for selling a hair tonic and dye that was found to tend to the production of eczema. In a number of instances the court seems to have thought it has done its duty when it has ordered the destruction of the injurious articles.

New Plans to Care for Sick Children.—It has been decided by the health board that communicable diseases would have to be treated further down the bay than at the new hospital erected on Ellis Island by the federal government, and in consequence an offer has been made to the city through Congressmen Goldfogle and Bennett that the city rent this hospital from the government for sick babies of the tenements. The mayor approves of the idea and is consulting with the commissioners of health and charities on the subject.—Dr. Lederle has issued a half a million posters entitled "How to Keep Baby Well," which he hopes will have an effect in decreasing the high infant mortality of the present season. These posters contain the usual advice and admonitions and are printed in several languages.—The dock commissioner has also come out with a plan to help sick babies. He wishes the unused space in the city terminal buildings at South Ferry used as open air hospitals. Each building has a space 75 by 100 feet which would be available and could easily be fitted up if the city would appropriate the money.—The health department will post the following placard in every place where milk is sold in the greater city: "For infant feeding use certified or guaranteed milk, or bottled pasteurized milk. If you use either bottled milk or milk from cans, either raw or pasteurized, the milk should be brought to a boil before feeding to the babies."

Buffalo

Personal.—Dr. Charles G. Stockton has gone abroad.—Dr. S. Y. Howell spent two weeks in July at the seashore.—Dr. George Haller is taking a trip up the St. Lawrence.

Infantile Paralysis.—The Buffalo Academy of Medicine is making an investigation concerning cases of poliomyelitis in the vicinity. All physicians having cases to report are asked to notify either Dr. Irving M. Snow or Dr. Lesser Kaufman who will supply them with proper blanks.

Buffalo Selected.—In a cablegram from Health Commissioner Fronczak, who is attending the International Congress on School Hygiene at Paris, the announcement was made that Buffalo was selected as the next meeting place in 1913. The convention is held every three years. The competing cities were Rome, Cologne, Prague, Brussels and Budapest.

Contagious Disease Hospital.—Another session of the board of common council has come and gone without a solution of the question of site for the proposed hospital for contagious diseases. In the meantime the epidemics, especially of scarlet fever and now of pertussis, go merrily on. The sum of \$18,000 is to be used to make the present makeshift hospital at least habitable.

Action on Death of Dr. Wende.—Resolutions adopted by the common council on the death of Health Commissioner Ernest Wende have been forwarded to Mrs. Wende by City Clerk Bailliett. The resolutions are morocco bound and bear the signature of every member of the common council. It was also voted by the common council to name the proposed hospital for contagious diseases the Ernest Wende Memorial Hospital. The medical profession sincerely hopes that this hospital will be so located, so built and managed as to prove worthy of the name.

Concerning Erie County Hospital.—After a public hearing on the matter of the proposed Erie County Hospital the committee of the board of supervisors has by request of the sub-committee on public health of the Chamber of Commerce and Manufacturers Club consented to postpone the final letting of contracts for six weeks. The proposition of the Chamber of Commerce is to have the city build a municipal hospital on the Driving Park site, of 825 beds and to include the proposed hospital for contagious diseases. The citizens of Buffalo look favorably on the project.

Whooping Cough.—Following the exceedingly great number of cases of measles there has been added an epidemic of pertussis. The health department is sending out sanitary inspectors to watch all boats, play-grounds and parks and will cause the arrest of all parents who break quarantine in cases of pertussis. There were 200 cases of pertussis reported to the department of health in July. This is a strong indictment against those who are opposing a hospital for contagious diseases because many of these cases are but a sequel of the tremendous epidemic of measles. During the past week there were seven deaths reported from whooping cough.

NORTH CAROLINA

Health Bulletin.—The Asheville City Board of Health, beginning May, has issued a monthly bulletin.

Shaw University Hospital.—Ground has been broken for the erection of a \$20,000 hospital at Raleigh for clinical instruction of the students of the medical department of Shaw University.

Personal.—Dr. George A. Mebane, of Mebane, was a contestant for the democratic nomination for Congress in the Fifth North Carolina District, being defeated on the 438th ballot after a session of the convention lasting six days, by ex-Lieut.-Gov. C. M. Stedman, of Greensboro. Dr. Philip Norris, of the Rutherfordton Hospital, was recently presented with a silver loving cup as a token of appreciation by the Rutherfordton baseball team.

Osteopath as Expert Witness.—In the trial recently in the superior court at Asheville, Judge Justice presiding, an osteopath was admitted and qualified as an expert medical witness in a case for damages against the Southern Railway, brought by a man whose child was struck on the head five years ago by a falling transom inside a car. The testimony of two reputable physicians, one an ex-president of the State Medical Society, who had examined the child recently, was that the child was in excellent health, bright, intelligent for his years, and they were unable to find anything of pathologic character warranting the maintaining of the action. The osteopath testified that as a "result of the blow and the shock induced thereby a thickening of the brain and a resulting dislocation of several vertebrae had induced 'petit mal' with which the child is now affected, though not in a manifest form." The jury returned a verdict for \$2,000 damages for the plaintiff.

PENNSYLVANIA

Personal.—Dr. B. Franklin Royer, Harrisburg, has been appointed chief medical inspector of the state, vice Dr. Arthur B. Moulton, resigned. Dr. Royer has been associate chief medical inspector for the past eighteen months.

State Railroad Commission's Report.—The quarterly report of the State Railroad Commission for the three months end-

ing June 30, shows that 271 persons were killed and 2,287 were injured on the steam railroads of Pennsylvania. There were during the same period 63 fatalities on the street railroads and 1,119 persons were injured. Of the fatalities on the steam roads, 89 were to employees, 11 to passengers, 143 to trespassers and 28 to others. The trolley lines killed 6 employees, 5 passengers, 7 trespassers and 45 others.

City Nurses Reduce Infant Death Rate.—Successful results have followed the city's campaign against infant mortality. Comparing the results in the second, third, fourth and fifth wards, where special efforts are being made to save the lives of babies, while the mortality last week was 7 per cent. higher than in the corresponding week of last year, as compared with the total increase of 50 per cent. for all the wards of the city, the work of the special nurses would mean a saving of 713 lives if it could be extended to all the wards of the city. In the second and third wards the mortality was 9 per cent. and 16 per cent. respectively, compared with 60 per cent. for the whole city; in the fourth and fifth wards it was 14 and 22 per cent., respectively.

Philadelphia

New Amphitheater for Woman's College.—Work will shortly be started on the new amphitheater for the Woman's Medical College on North College Avenue. The building will be used for clinical work and will consist of a two-story brick structure, 35 by 40 feet. The estimated cost is \$17,500.

New Laboratory for the University.—Architects have completed plans for a new zoologic laboratory for the University of Pennsylvania. It is to be a three-story, fireproof building, occupying a lot 216 by 156 feet on Hamilton Walk, adjacent to the old biologic laboratory and its cost will be about \$300,000.

Hospital Opens a Milk Station.—On July 28 a modified milk station was opened at the Mt. Sinai Hospital, to be maintained throughout the year as part of the general plan inaugurated for the better care of babies in the tenement districts. The station will be open daily from 9 to 11 a. m. and from 5 to 6 p. m. Special nurses will be on hand to advise mothers.

Another Baby Station Opened.—Another baby-saving station was opened by the city August 3 on the Race Street recreation pier, where a day nursery and hospital will be conducted by the department of health and charities. One end of the pier is equipped as a hospital for babies and a rest room for mothers, and the other is fitted up with a sand pile and playthings for older children.

Personal.—The following physicians have sailed for Europe: Dr. D. Roman, on August 3; Drs. Walter C. Stillwell, Arthur Jackson Brewe and J. I. McGuigan on August 6. Dr. Willis F. Manges has been named as chief of the Roentgen ray laboratory of the Philadelphia General Hospital to succeed the late Dr. Mihran K. Kassabian whose death was caused by x-ray burns. Dr. Manges has had charge of the x-ray laboratory at the Jefferson Medical College and will continue in that position. Dr. Edward A. Leonard has been promoted to assistant physician at the Philadelphia General Hospital, made vacant by the resignation of Dr. Samuel Stern. Dr. Joseph F. Dunn has also been appointed assistant physician at the Philadelphia General Hospital. Dr. Joseph Price, who has been ill for six months from septic poisoning, has recovered and is again at work.

University Adds Course in Tropical Medicine.—Announcement was made August 5 that the University of Pennsylvania would add a series of courses in tropical medicine as an elective to undergraduates and as a special course to post-graduates. These courses will be under the charge of Dr. Allen J. Smith, dean of the medical department, and they will include instruction in medical climatology and geography; hygiene of ships and of the tropics; protozoology, anthropology, helminthology and general medical zoology; diseases of the eye, skin and surgical diseases common to the tropics; pathology of tropical diseases and systematic and clinical tropical medicine. The full course will continue fifteen weeks and will include ten units of study. The teaching force of the department will include Drs. A. C. Abbott, William Pepper, George E. de Schweinitz, William B. Hartzell and M. H. Jacobs.

Druggists' Association Acts Against Soothing Syrups.—At a meeting held in the College of Pharmacy on August 5, the

Retail Druggists' Association passed resolutions condemning so-called soothing syrups containing morphin and cocaine. Eleven hundred druggists, members of the association, will now refuse to sell syrups without a physician's order and are determined that any infringement of this rule shall be punishable by loss of membership in the society. Under the auspices of the state pharmaceutical board, an active campaign will be begun against the sale and manufacture of such pernicious drugs. The state legislature will be appealed to at its next session to eliminate from the statute books the present law which permits the sale of these drugs, providing that their contents are made clear on the labels of the bottles, and to insert in its place a clause which shall prohibit entirely the manufacture of the concoctions.

Campaign Against Tuberculous Meat.—Dr. A. H. Schreiber, chief meat and cattle inspector of the Health Department, announced on July 25 that warrants would be issued this week for the arrest of persons charged with selling tuberculous meats. Of the dealers selling meats without a license, fourteen have been arrested and were arraigned before Magistrate Beaton, July 25. Each was fined \$2.50 and costs and ordered to secure a license at once. Six slaughter houses in West Philadelphia have been closed by the Board of Health and fifty additional warrants issued for meat dealers because of the insanitary conditions which prevail and because they failed to meet the requirements of the law in slaughtering cattle, in the disposal of offal and in keeping the premises in clean condition. During one week since the inauguration of the campaign 1,500 pounds of beef and mutton were destroyed because it was unfit for food. Most of this was found on the counters of small dealers and was confiscated by the inspectors.

Women to Aid Phipps Institute Work.—Alexander M. Wilson, sociological director of Phipps Institute, announced August 3 the appointment of three women assistants who will work in the social service of the dispensaries. They are Miss Janice S. Read, of Worcester, Mass., who for three years was head resident in the Jewish Sisterhood Neighborhood House, Newark, N. J.; Miss Lillian G. Elbridge, a graduate of Vassar College and formerly of the Girls House of Refuge, Philadelphia, and Miss Edith Dudley, Poughkeepsie, N. Y., graduate of Wellesley and also a worker in the House of Refuge. Their work at the institute is to attempt to better the conditions under which the dispensary patients live. They will see that children in families where there is tuberculosis are protected against infection, and if already infected, that they are placed under proper treatment. The help of the health department, of landlords, employers, churches and charities will be enlisted to obtain good surroundings and sufficient diet for the patients that come under their charge.

RHODE ISLAND

Medicolegal Society Meeting.—The annual meeting of the Medicolegal Society of Rhode Island was held at Field's Point, July 22. Dr. Arthur H. Harrington, Howard, was elected president, and Dr. Carl R. Doten, Providence, secretary-treasurer.

Building for State Medical Society.—The Rhode Island Medical Society, at its last annual meeting, appropriated \$7,500 for a building for permanent headquarters of the society, and has purchased land at the corner of Hayes and Francis Streets, Providence, for the purpose.

State Health Officers Meet.—The health officers of the cities and towns of the state met at the State Hospital, Providence, July 28. Quarantine and water supplies were the chief topics of discussion. Dr. John H. Bennett of the State Board of Health, spoke of the subject of fumigation, stating that from his experience, he believed the best kind of fumigation was that which brought into use fresh air, sunlight, hot water and soap and plenty of elbow grease. A committee was appointed consisting of one health officer from each county to draw up an acceptable and effective quarantine bill for presentation to the next legislature.

Work of the State Sanatorium.—At the opening of the tuberculosis exhibit under the auspices of the Newport Association for the Relief and Prevention of Tuberculosis, Dr. Harry Lee Barnes, superintendent of the State Sanatorium, stated that the state sanatorium had saved lives with sufficient frequency to amply justify its establishment financially, even

though the humanitarian consideration be ignored, and that investigation had shown that the annual earnings of patients discharged from the institution during or before 1908, and who are free from active symptoms of tuberculosis, had amounted to over \$100,000.

WASHINGTON

State Medical Society.—The Washington State Medical Association met at Bellingham July 26, 27 and 28. One of the sessions of the convention was held on a steamer, cruising among the San Juan Islands. Hon. Horace E. Hadley, justice of the supreme court of Washington, addressed the convention on "The Joint Responsibilities of the Lawyer and the Doctor." The following officers were elected: President, Dr. Wilson R. Johnson, Spokane; president-elect, Dr. Leon L. Love, Tacoma; vice-presidents, Drs. Grant Calhoun, Seattle, and J. Earl Elsie, Pullman; secretary, Dr. Curtis H. Thompson, Seattle; treasurer, Dr. Park W. Willis, Seattle, and delegates to the American Medical Association, Drs. James R. Yocom, Tacoma, and George W. Libby, Spokane. The next meeting will be held in Spokane.

WISCONSIN

Personal.—Dr. Lewis F. Bennett, Beloit, has been elected president and Dr. John M. Bessel, Milwaukee, secretary of the State Board of Medical Examiners.—Dr. Frank E. Darling, registrar of vital statistics of the health department of Milwaukee, has resigned.

Nurses Call for Tuberculosis Instruction.—The Wisconsin State Association of Graduate Nurses, at a recent meeting, adopted resolutions calling on training schools to furnish adequate instruction in caring for tuberculosis patients in homes and in institutions. The action is approved by the Wisconsin Antituberculosis Association.

Milwaukee Health Conditions.—During the week ended July 23, Health Commissioner William C. Rucker, reported that there were 222 cases of typhoid fever, a decrease of 19 since July 16. Forty-nine new cases of typhoid were reported, five deaths were assigned to that disease and 63 recoveries. The work of gathering samples of water from the lake for the state hygienic laboratory has continued for the past six weeks. Water has been taken at intervals of from one mile to a distance of seven miles in the lake. Commissioner Rucker has been criticised for not making public the reports of the examination of water but the commissioner claims the blame is due to the fact that the reports are in the hands of the printer. The investigation conducted by George C. Whipple, an expert from the New York Sewerage Commission, with the assistance of the city engineering department has shown that there is no leak in the intake pipes near the shore. The reports of Commissioner Rucker and the reports of the analysis by the state hygienic laboratory are awaited by the public with much interest.—The recent test of ice-cream shows that manufacturers are complying with the law regarding the standard for ice-cream.—Health Commissioner Rucker has recommended that the department of Dr. George P. Barth, school physician, should be enlarged by providing visiting nurses to go to the homes and teach hygiene to the parents of the pupils.—The Seventh Street Isolation Hospital which has previously been condemned as unfit for hospital purposes, will be abandoned and the building in Kern Park will be used temporarily for isolating diphtheria, scarlet fever and measles.

TEXAS

New Wing at Insane Asylum.—A new wing at the Southwestern Insane Asylum at San Antonio was opened recently and 100 additional white patients have been admitted. The completion of the new wing makes room for 300 more patients.

Salaries of Health Officers.—The state board of health advocates better salaries and longer terms for the city health officers in the various cities of the state. The board believes that this should be conducive of more efficient work in health and sanitary matters.

GENERAL NEWS

Infant Mortality Association Meeting.—The first annual meeting of the American Association for the Study and Prevention of Infant Mortality will be held in Baltimore Nov. 9 to 11. The sessions will embrace municipal, state and federal

prevention. Dr. William H. Welch will preside. The following are chairmen of committees: Medical prevention, Dr. L. Emmett Holt; educational prevention, Dr. Helen C. Putnam; philanthropic prevention, Dr. Hastings N. Hart. There will be a large exhibit, embracing milk, work, clothing, diet, hot-weather care and recognition of early conditions of disease. Membership is open to all who are interested in the baby. Miss Gertrude B. Knipp, medical and surgical faculty building, Baltimore, is executive secretary.

Cost of White Plague War.—According to the report issued by the National Association for the Study and Prevention of Tuberculosis the average cost of caring for tuberculous patients in thirty semi-charitable sanatoriums scattered throughout the United States is \$1.67 per day. The expense of maintaining the institutions in different parts of the country varies from 94 cents per capita to \$2.56, being more than twice as high in the west and southwest as in the east. The aggregate expenditure was \$1,364,000 and the receipts \$1,548,000, 70 per cent. of which came from public appropriations and private benefactions and the remainder from patients. It is estimated that there are 300,000 indigent consumptives in the United States who should be cared for by the state, which at the rate named above would cost \$50,000,000, though the economic loss from the incapacity of these afflicted persons is yearly \$200,000,000.

FOREIGN

Seven Physicians in Hungarian Parliament.—Four new medical members were recently elected, making a total of seven physicians at present in the Hungarian parliament.

Italian Malaria Journal.—The Italian Antimalarial League has founded a journal, *Malaria e Malattie Affini*, to be devoted to work and news bearing on malaria. The address of the new journal is via Farini 62, Rome.

Hydrophobia Statistics in Argentina.—According to the *Semana Medica* of June 23, during the twenty-four years since the Pasteur Institute at Buenos Aires was opened, more than 10,000 persons have taken a course of treatment, 73 have died, a total mortality of 0.67 per cent.

Laboratory for Research on the Brain.—A Moscow medical society, whose aim is to promote the experimental sciences, has turned over to Professor Pawlow an endowment of several thousand dollars to equip a laboratory for special research on the brain.

Pensions for Widows and Orphans of Basel Professors.—On the occasion of the four-hundred and fiftieth anniversary of the founding of the University of Basel, Switzerland, an endowment of \$70,000 was collected by the academic society for pensions for the widows and orphans of instructors at the university.

The Recklinghausen Endowment.—Professor von Recklinghausen retired in 1906 from the chair of anatomy at the University of Strasburg, after 35 years' incumbency, as mentioned in these columns at the time. His former pupils have been collecting subscriptions for an endowment to bear his name. The fund has now reached the sum of nearly \$4,000 (14,500 marks), and was recently presented to him to apply as he sees fit.

Honors to a Belgium Practitioner.—The fiftieth professional anniversary of Dr. Cartier was recently celebrated at Herstal near Liège, the entire population joining in the demonstration. The *Gazette méd. Belge* says that the town was gaily decorated, bands played, the chimes were rung and crowds thronged the city hall all day long, all in honor of Dr. Cartier's fête. The local authorities, industries, charities, lodges and the medical profession each paid tribute to his half-century of devoted service.

Memorial to Spanish Medical Officers.—A large memorial tablet, commemorative of the Spanish military physicians who lost their lives in the recent wars, was unveiled June 25 in the presence of a large gathering including the royal family and officials. The memorial is in the main hall of the military hospital and the *Siglo Medico* of June 25 gives the list of names of the physicians as inscribed on the tablet, with their rank and place and date of decease, from 1834 to 1895. After this date are the names of Dr. Molto, Noveleta, 1897, and Dr. Carraceja, 1898, corresponding to the date of our war with Spain, and Don Pascual, Peñon de la Gomera, 1909, a total of 24 names in all.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, July 30, 1910.

Annual Meeting of the British Medical Association

The seventy-eighth annual meeting of the British Medical Association was held in London July 22 to 29. It is now 15 years since the association met in the metropolis, which offers unusual advantages for the purpose, among which is an unusually large attendance, on this occasion amounting to 3,000. The function was in every way—scientific and social—most successful. Among the foreign guests were Prof. Koehler (Berne), Dr. Lucas Championnière and Dr. Wickham (Paris) and the following Americans: Dr. J. H. Bryan, Dr. Bulkley, Prof. Crile, Prof. Tait Mackenzie and Dr. Edsall. The president, Mr. Henry T. Butlin, who is also president of the Royal College of Surgeons, delivered a very interesting address on "The Evolution of the Association and Its Work." The growth of specialism has increased the number of "sections" of the association to 21, which now includes such new ones as "Medical Sociology" and "Radiology and Medical Electricity." Ample accommodation was furnished by the spacious class rooms of the University of London. The sections were well attended and many papers of great interest and importance were read and discussed. In the Section on Surgery, Mr. Arbuthnot Lane advocated the operative treatment of simple fractures. His name has long been identified with this method and his views have been previously published in THE JOURNAL. The discussion revealed considerable difference of opinion. Dr. Lucas Championnière of Paris could not agree with the utility or necessity of the method in all cases. Mr. Gilbert Barling found it difficult to reconcile the divergent views now held as to the treatment of fractures. Some claimed that by non-operative methods it was possible to obtain a high percentage of perfect results; others that after an ordinary fracture treated by splints there was a depreciation ranging from 30 to 100 per cent. He suggested that a committee be formed to investigate the matter. A resolution in favor of this was passed by the section.

Dr. Louis Wickham of Paris gave a demonstration, illustrated by lantern slides, on the treatment of cancer by radium. He showed the remarkable effects of radium in causing the regression and even disappearance of cancerous growths but deprecated the use of the word "cure" which should rarely be used. In the great majority of cases radium should be associated with surgery. If a grave cancer was present the radium therapist should first consult the surgeon so that the patient be not deprived of the prompt help of surgery. On the other hand, if the surgeon has a case in which it is difficult to operate he should use radium to prepare the ground and diminish the virulence of the growth. He should also prepare the ground for the action of radium, by perforations, incisions, and by partial extirpations diminish the thickness of the tissues which the rays have to traverse.

In the Section on Dermatology Sir Jonathan Hutchinson read a paper on "Paleogenesis as Illustrated in Certain Affections of the Skin." This is an entirely new subject which this wonderful octogenarian has attacked with an energy and originality which show no sign of age. Paleogenesis is a name which he has introduced to signify inheritance from remote ancestors in the evolution of man from the lowest types. The term atavism has been used to signify inheritance from near progenitors. Paleogenesis is therefore atavism in *cœclsis*.

For the ordinary visitor the most important and interesting feature of the meeting was the scientific exhibit which surpassed all previous exhibits in elaborateness. It contained over 3,000 specimens and was organized on a new plan, being divided into 19 sections, each under the care of an expert honorary curator, who selected a few subjects for illustration and collected from all available sources the most useful material. Thus the exhibit contained many series of exhibits rather than the usual miscellaneous items. Special attention was paid to methods, and as far as possible an ocular demonstration was offered of recent advances and of methods employed both in practice and in the laboratory for the diagnosis and treatment of disease. A novel feature was a section devoted to anesthetics in which many historical as well as modern anesthetic apparatus were collected. The number of microscopic specimens shown was unusually large, amounting to over 400. The section of protozoology was most interest-

ing; many recently discovered parasitic protozoa were shown in the blood of man and animals. In the Section on Cancer Research the ethnologic distribution of the disease and cancer in animals, spontaneous and transplanted, were illustrated. A very interesting series of portraits with accompanying microscopic sections showing the condition in cases of cancer before and after the use of radium, was exhibited by Dr. Dominici of Paris. Under the influence of the radium the growths disappeared and on microscopic examination the epithelial cells of the cancer were shown in process of regression and replacement by connective tissue.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, July 28, 1910.

Pyelotomy for Removal of Renal Calculi

On July 26, Dr. Bazy, surgeon of the hospitals of Paris, read an interesting paper before the Académie de Médecine, showing that the removal of most renal calculi may be effected by pyelotomy, that is, the incision of the kidney pelvis alone without injuring the parenchyma of the kidney, without disturbing the functioning of the organ, whatever it may be, and without altering its functional value. Bazy believes that it is unnecessary in the great majority of cases to make patients undergo exploratory operations, which may be badly sustained or dangerous, in order to ascertain the functional value of the kidney. Pyelotomy may be performed on any person capable of undergoing an operation of average duration and of minimum gravity. It is entirely suitable in cases in which the kidney containing the stones is the only functioning one and therefore must be conserved. These conditions were present in two of Bazy's patients, women aged 48 and 58, respectively, and worn out by suffering. Pyelotomy may be employed in cases in which the kidney pelvis is infected. The reunion of the pelvis by first intention does not appear to be hindered by this complication. It may be ascertained in advance by radiography whether one should employ pyelotomy or nephrotomy.

Enlargement of Scope of Scientific Information Bureau

For about seven years there has been at the Sorbonne a bureau of scientific information for foreign students. Up to the present this service has been maintained by the municipality of Paris. To improve this service, an association has been recently formed to furnish to all, whether French or foreign, but especially the latter, by correspondence or orally, all useful information in regard to the means of study in France. It will organize tours of study for foreigners in France, will aid in the formation and development of special courses in the universities for the use of foreign students, and will organize outside of France, an active propaganda in favor of French instruction, through brochures, prospectuses, newspaper articles, diplomatic agents and special correspondents, etc. It will also encourage relations between professors and students in French and foreign universities. While up to the present, the bureau of information has been almost exclusively Parisian, the field of the new organization, which is called Office national des Universités et grandes Ecoles françaises, will cover the universities in the departments. The government has voted \$2,400 (12,000 francs) in aid of this institution. [Address: Bureau des Renseignements Scientifiques, Sorbonne, Paris, France.]

Medals for Physicians Who Do Vaccination.

It is customary each year for the Académie de Médecine to award gold, silver-gilt, silver and bronze medals to physicians who do vaccination. These medals are transmitted to the minister of the interior and then sent to the prefects, who send them to the physicians thus honored. This year several medals did not arrive at their destination. Inquiry brought out the fact that certain prefects had confiscated the medals because the physicians to whom they had been awarded were not in agreement with the government. Indignant at this intrusion of politics into a matter with which it had no concern, the council of the Académie de Médecine brought the matter before the premier, M. Briand, who has energetically censured the culprits and has promised that the physicians who had been awarded medals shall very shortly receive them.

The Illegal Practice of Medicine by a Physician

According to French law, the physician who lends his countenance to a person practicing medicine without a diploma or who, without directing the treatment of the patients, uses his medical degree to lend sanction to the acts of such a person, becomes guilty of illegal practice of medicine. Recently the courts have decided that a physician who directs the treatment himself but who prescribes for many of the patients on the basis solely of replies to questions published broadcast, in the name of some institute or other, is thereby aiding the illegal practice of medicine.

The Period of Military Instruction to Students

Because of the inconvenience caused to students by the obligation of responding to the call to military instruction at the time of an examination, of a *concours* or of matriculation at a college, the minister of war has informed the generals commanding the army corps that it would be advisable for them to receive as favorably as possible the requests for delay made by students when the latter show that it would be impossible for them to absent themselves from their studies without serious detriment.

Election of Two Associates to the Academy of Medicine

The Académie de Médecine has elected as national associates Dr. P. Spillmann, professor of clinical medicine at the Nancy College of Medicine and Dr. Testut, professor of anatomy at the Lyons College of Medicine.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, July 20, 1910.

The Fossil Races of Men in Europe in the Glacial Period

Professor Klaatsch, the well-known Breslau anthropologist, delivered recently a very interesting address in the medical section of the Schlesische Gesellschaft für Vaterländische Kultur on the oldest races of men in Europe. By the recent discoveries the views regarding the relationship of man with the apes have been much modified. In many points the apes go beyond man. The long arms and strong canine teeth are phenomena of adaptation which developed after the path toward human development was closed to the ape. There must have been a common road from which the various paths of development separated. The hand with long thumb is the original form; even the four-footed animals have developed from quadrumanous types. It is also established by the newest discoveries that the variety of races is an ancient phenomenon. Probably a continent between Asia and Africa has sunk and in that way a separation into the African type (gorilla) and the Asiatic type (orangutang) arose. The prehistoric man discovered at Aurignac appears to represent a younger race than the Neandertal man and the man of Le Moustier. A complete skeleton, beautifully preserved with petrified bones, was unearthed at La Chapelle, France. It shows a complete burial with the face directed toward the south, and in addition some remarkable tools; also a shell ornament was found about the neck. The skeleton was that of a slender human being, but with primitive characteristics like those of the Australian race. The *Faustkeile* indicates the oldest period of the glacial drift, at any rate older than the discovery of Le Moustier and Aurignac. The lecturer regards the Neandertal man as of African type and the man of Aurignac as of Asiatic type.

Ehrlich's New Syphilis Remedy, "606" *

Good results with the new remedy have been reported from some hospitals during the last week. Of greater importance is an improvement in technic which Dr. Weichselmann, the director of the dermatologic department of the Virchow hospital in Berlin, has made and will soon publish. Of the two side-effects which have so far been observed after intramuscular injection of the remedy, namely, rise of temperature to 39 C. (102.2 F.) and the pains, the latter are more

* This subject is discussed editorially in this issue and also in the Budapest letter, page 610, and in the Miscellany Department, page 617.

disagreeable, as the fever lasted only a short time, while, after an intragluteal injection, severe neuralgic pains in the region of the sciatic were felt for several hours and required repeated injections of morphin. In some cases pains persisted in the sciatic region, of a light or medium severity, for several days. The technic of Wechselsmann is intended to avoid this disagreeable complication. The remedy "606" is dissolved in commercial soda lye by rubbing in a mortar; on addition of glacial acetic acid, drop by drop, a fine yellow precipitate falls which is suspended in some distilled water and the reaction of the liquid is made exactly neutral to litmus paper. The suspension is then slowly injected below the shoulder blade, the skin having been previously disinfected and painted with tincture of iodine. Sometimes a slight pain from the injection occurs for a few minutes and occasionally there is a slight swelling on the second or third day. No complaints of moment have occurred in from 60 to 70 cases and there has been no rise of temperature. The action of the remedy remains undiminished. This technic has the advantage that in case symptoms of arsenical poisoning manifest themselves, the site of the injection may be easily cleaned out.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, July 25, 1910.

An Acoustic Museum and Its Scientific Use

The royal and imperial Vienna Academy of Sciences (Akademie der Wissenschaften) the most renowned Austrian scientific corporation, has possessed for a few years a unique collection of phonograph records, which contain, besides the voices of remarkable persons, numerous records of ethnographic and scientific value. Some of the latest additions come from the voyage of Dr. Püch, who has taken great pains to obtain characteristic sayings and songs of the Bushmen. The nature of their guttural language can be examined by means of the records by magnifying the vibrations produced by any small part of the cylinder, and observing the succession of vibrations by means of a reflecting mirror. Thus it could be shown that, for instance, the vowels of the language of the Bushmen differ from those of the Papuans, and that the note of the frog, which very much resembles the "ah" of the human voice, is caused by a succession of definite short acoustic impulses, not like the human "ah." The examination of voices in different pathologic conditions of the throat and larynx has also been undertaken by means of the graphophone, and the results of 1,000 various investigations will be published shortly.

The Ultimate Fate of Hereditary Syphilitics Among the Better Classes

Dr. Hochsinger at a recent meeting of the Gesellschaft der Aerzte in Vienna, discussed the results of a series of investigations, extending over twenty-five years, into the ultimate fate of children whose parents had contracted syphilis before the children's birth. Only the better classes of the population were considered and of these only families in which the doctor had opportunity of constantly observing parents and children for a long period. The results are rather unexpected. Altogether, 139 families with 569 children were observed. The 139 women had 263 syphilitic infants born alive, 253 dead babies and 53 living non-syphilitic children. Of the 263 affected children born alive, 55 died before reaching the age of 4, so that 208 individuals were the subjects of prolonged observation. Only 25 per cent. of all of them remained alive and without any attacks, and only 14 per cent. of the children died within their first year of life. All other patients have shown during their life, symptoms of disease traceable directly to syphilis. Apart from manifestations on the skin and the mucous membranes, especially affections of the nervous system, together with moral insanity, were most frequent. The well-known fact that hereditary syphilis plays a prominent part in the etiology of these conditions is borne out very well. On the other side, it was shown that if hereditary syphilitic persons remain healthy up to the age of puberty, the expectation of a healthy future life is justified. Recurrences of syphilis have a very deleterious influence on the somatic resistance of the children; 79 children out of the 263 died during the observation; of course the majority of the deaths occurred within the first year. The most affected organs were the lungs and the alimentary canal.

According to the statistics of hospitals with their badly fed unhealthy applicants 70 per cent. of all syphilitic babies die in their first year. Dr. Hochsinger's observations deal with better families, where every possible care was available for the children. The most frequently attacked organs were in the new-born, the skin, the nose, then the viscera. The first-born child is generally more severely attacked than the second, this more than the third and so on. Also the number of recidives declines with the increasing number of children. Out of 123 first-born children, 93 (or 73 per cent.) had recurrences; out of 55 second-born babies, only 24 (or 45 per cent.) had recurrences, and out of 21 third children only 8 (or 38 per cent.) had recurrences. Where maternal lues was manifest, the children most often had developments of the disease, showing that the maternal manifest affection seriously influences the fate of the children. The characteristic feature of the late hereditary syphilis was always the gumma; infantilism and general maldevelopment were frequent. Chronic headache, migraine, is a very frequent concomitant, and very often a characteristic feature of hereditary syphilis. The absence of Hutchinson's symptom, as well as the fairly favorable results during the observations seem to show that an energetic long-continued antisyphilitic treatment may do much good for the unhappy offspring of a tainted family.

BUDAPEST LETTER

BUDAPEST, July 14, 1910.

Outbreak of Typhoid in Budapest

A serious outbreak of typhoid fever has occurred in Budapest, and although officially the nature of the disease has been kept secret, the actual facts became known very soon. Last week over 500 cases were reported, of which 200 are in public hospitals; the remainder have been left in family care. The epidemic was not due to the condition of the water, as has been proved satisfactorily. The majority of the cases were caused by contamination of the milk imported into the city from certain districts; some were traced to the consumption of contaminated fruit, butter and soft cheese. Articles of food are brought to the market in Budapest in a scandalous condition, the danger of which has been often pointed out. Recently out of 200 samples of food taken from as many retail sellers, not less than 60 were found to be unfit for consumption and therefore the lot had to be seized and destroyed. Typhoid has always been present in the city during summer, but the cases were few, far apart and could easily be controlled. At present the epidemic is undoubtedly local, imported from the suburbs, and could be speedily checked if only the market authorities could exert the necessary control over the importation and sale of milk and fruit. Lately, but too late, draconic measures have been instituted in regard to cleanliness.

Ehrlich's New Remedy for Syphilis *

Perhaps nowhere has Ehrlich's discovery caused greater agitation than in Hungary. The dailies devote whole pages to it, not sparing epithets or adjectives in praise. One of the dailies even sent two doctors to Frankfort, where Dr. Ehrlich is working, in order to study the new methods.

As a result of the publicity thus given to this new method, physicians are besieged by patients, imploring to be cured. But, alas! Dr. Ehrlich has not yet brought his remedy to that stage of perfection which allows of its administration without danger, so that he feels himself obliged to confine its use to hospitals, where the patient is under uninterrupted observation, to the present exclusion of private practitioners. The most important Hungarian hospitals have already sent their representatives (some to Frankfort to Dr. Ehrlich and some to Berlin to Dr. Wechselsmann) to study the manner of conducting the treatment in the hospitals there.

As I was one of those who called on Dr. Ehrlich, I am able to relate personal experiences regarding this discovery. When I was admitted to Prof. Ehrlich's laboratory I was surprised to see three men in a little cabinet writing at Ehrlich's dictation. I questioned him as to the reason of this. "You

*This subject is discussed editorially in this issue and also in the Berlin letter, page 609, and in the Miscellany Department, page 617.

see," said he, "that although I feel very much flattered by the attention and confidence displayed in me by my brother physicians, yet I cannot reply to all the demands they make on me. I myself am not a practitioner, but the director of the *Königliches Institut für experimentelle Therapie* (Royal Institute for Experimental Therapeutics). I am investigating in my laboratory and have placed the experimenting and proving of this remedy into the capable hands of Dr. Wechselsmann at the Virchow Hospital in Berlin, where he is studying cases under treatment. However, I wish if possible to answer all letters and telegrams (and they come by the basketful), and that is what you now see me attempting to do. There are some letters here that have had to wait for three or four weeks.

"As to the method of discovery, it has not been like so many other new discoveries, a matter of chance, but I have been working at it for some time past, knowing as I do how many are suffering under the fear and apprehension of this terrible disease, and that if I could succeed in alleviating this I should feel satisfied and consider that I had accomplished a beneficial work. As my friend, Dr. Wechselsmann, says, referring to the treatment, one injection arrests the disease to as great an extent as more than a year's treatment by any other method.

"The most important point about this remedy is that one injection utterly destroys all the spirochetes, but is harmless to the animal tissues. In the course of my investigations I have made hundreds of mixtures with which to accomplish this, but only after several years of experiments did I, in company with Dr. Hata, in November last, discover the present medicine 'dimethyldioxiarsenobensoldichlorhydrat' and the cure 'sterilisatio magna,' so called because of its 'great effect of killing all parasites at once. In March last, being so satisfied with the results of my trials on animals, I decided to apply the medicine to human beings, but having no hospital under my control, I asked my friend, Dr. Wechselsmann, to undertake the conduct of the experiments, and he, I am sure, will be very pleased to show you the method and the results if you go to Berlin."

I went to Berlin to the great Virchow Hospital, where Professor Wechselsmann has charge of the venereal section. Wechselsmann's section was located by the innumerable eyeglassed gentlemen who were standing before the door of a large building. It was not difficult to find out that these doctors were waiting for Wechselsmann. It was then 9:40 a. m. Exactly at 10 o'clock Professor Wechselsmann came. He is a man about 50, who displays all the external features of a learned man. He was glad to see, he said to me, after my introduction, that the Hungarian doctors are so keen in appreciating the epoch-making importance of Ehrlich's new remedy. "The lay press," he said, "is in great measure responsible for this extraordinary interest. You are the thirteenth Hungarian to come to see our work here." Then he showed us his wards, which are the model of a modern hospital. Large spacious halls of spotless cleanliness, glazed, tiled, cornerless walls, electric ventilation, good light; in short it is the acme of hygiene we see here. He led us into a separate compartment where about 12 patients were located, all treated with Ehrlich's remedy. He showed us one case, which was admitted 6 days previously, with a fresh syphilis, papules, swollen glands and mucous plaques in the throat. All these symptoms had disappeared after one injection of the Ehrlich remedy, which was administered four days before. And this is not an exceptional case, he said, because all patients who were treated with amido-arseno-benzol, were just as favorably influenced by this remedy. It is true that some of the patients complained of great pains, and in some exceptional cases even urticaria-like rashes made their appearance, and even for three or four hours after the injection fever may occur; however the patients do not mind such little inconveniences considering the great advantage they derive from the injection. "As yet," he said, "I have tried the remedy, almost without exception, in fresh cases, so that for the time being I am unable to say anything definite about old neglected cases. However, I heard from a friend of mine, who has charge of over 200 syphilis cases, that he has had good results with tertiary lues cases, too. At the Neppspringe Lunatic Asylum, for patients whose nervous break-down could be traced back to a syphilitic origin, Ehrlich's remedy was

applied with the most surprising results." He finished his very interesting lecture and demonstrations with the assertion that he would not give Ehrlich's remedy into the hands of private practitioners until 3,000 cases were reported on, which is probably nearly at hand, because nearly 2,500 phials were already distributed, and Ehrlich does not give his remedy to anybody without an agreement in writing that the physician will send him a report of the results. "Mention me to your science-loving countrymen," he said, in finishing his interesting discourse.

Dissatisfaction with a University Appointment

Considerable dissatisfaction has been manifested in the medical and lay press, as well as by the public, toward the appointment of L. Nekam to the chair of dermatology in the University of Budapest on the recommendation of Count Fiehy, minister of public instruction, whose appointment has been sanctioned by Emperor Francis Joseph. The committee of the medical faculty had proposed the names of Drs. Török and Marschalko, to the general board whose duty it was to investigate and report on the applicants. This body entrusted this duty to a theologian, who ignored the proponents of the medical faculty and appointed Dr. Nekam, with the resulting dissatisfaction.

Creation of Five New Universities

At the present time there are only two universities in Hungary, those at Budapest and Kolozsvár. The former is so crowded with students that proper attention cannot be given them. The authorities have been endeavoring for many years to have different cities assist in establishing other universities, but the matter has never taken practical shape. It is the intention of the present legislative body to establish five universities at once in different parts of the country, two of which shall have medical faculties. These will be built in Szeged and Kassa, two flourishing towns in opposite corners of Hungary, lying outside the circles of the two existing universities. It is hoped that this will relieve the crowded condition of the University at Budapest, which has 1,600 medical students, with accommodations for only 1,200. The two new universities having medical departments are expected to be ready by September 1, 1912.

Yaws and Syphilis.—Henry J. Nichols, Medical Corps U. S. Army (*Proc. N. Y. Path. Soc.*, February and March, 1910), states that in 1905 Castellani while examining smears from a case of yaws discovered a spirochete which when afterward stained with Giemsa stain seemed to be identical morphologically with the *Spirochæta pallida*, and this opinion was confirmed by Schaudinn. Castellani named this *Spirochæta pertenue* or *pallidula*. Castellani inoculated three monkeys, and in one after sixteen days, at the site of inoculation, a yaw-like lesion developed which repeatedly showed *Spirochæta pertenue*. Although Castellani and Schaudinn found no morphologic difference between the *pertenue* and the *pallida*, Prowazek believes that there are certain differences between them. The *pertenue* is slightly thicker and less rigid; the twists are not so regular; there is more of a tendency for the ends to curl up; the forms with longitudinal divisions are more numerous. After careful study and experimentation the evidence against the identity of the disease with syphilis seems to be as follows: 1. Geographical distribution; yaws is confined to certain tropical regions; it exists where there is no syphilis, and has also died out while syphilis remained. 2. Yaws and syphilis may occur in the same person, and there is no immunity from one disease to the other. 3. The lesions in yaws are always the same, not pleomorphic. 4. The lesions of yaws affect principally the epithelial, not the connective tissue. 5. Yaws is principally a disease of children but is neither hereditary nor congenital. 6. The lesions are extragenital and sexual transmission is practically unknown. 7. Constitutional symptoms are not the rule in yaws. 8. The treponemas may differ morphologically.

Marriages

HUGH O. JONES, M.D., Chicago, to Miss Nettie Perry, of Oshkosh, Wis., July 27.

GEORGE GILL, M.D., to Miss Adele Hieber Bassett, both of Elyria, Ohio, July 25.

JOHN BUSHROD SCHWATKA, M.D., to Miss Nina M. Duvall, both of Baltimore, July 30.

DANIEL E. RICARDO, M.D., Chicago, to Miss Justine Theresa Friend, of Cincinnati, August 1.

MORRIS I. BAYLIN, M.D., Baltimore, to Miss Pauline Shulman, of New York City, July 17.

FRANK BLAIR LOVELL, M.D., Gibson City, Ill., to Miss Helen Lewis Brewster, of Wheaton, Ill., June 30.

WALTER ANDREW BLOEDORN, M.D., U. S. Navy, to Miss May H. Howard, of Washington, D. C., July 25.

WILLIAM SCOTT WADSWORTH, M.D., Philadelphia, to Miss Frances Elizabeth Diel, of Syracuse, N. Y., August 4.

Deaths

Charles Jewett, M.D. College of Physicians and Surgeons, New York City, 1871; a member of the American Medical Association; American Academy of Medicine; American Gynecological Society; International Periodical Congress of Obstetricians and Gynecologists, and British Gynecological Society; president of the Medical Society of the State of New York; gynecologist and obstetrician to the Long Island College Hospital; consulting obstetrician to Kings County Hospital; consulting surgeon to St. Christopher's Hospital; consulting gynecologist to Bushwick, Swedish and German Hospitals and Bushwick and Eastern District Dispensaries, Brooklyn; professor of obstetrics and gynecology in Long Island College Hospital; died at his home in Brooklyn, August 5, of apoplexy, aged 71. Dr. Jewett was at the time of his death president of the Medical Society of the State of New York and of the Kings County Medical Society and had been one of the most prominent practitioners of Brooklyn for many years. Although 71 years of age he was in active practice up until a few days ago.

James Albert Hawke, M.D. University of Pennsylvania, Department of Medicine, 1863; a veteran of the Civil War; who entered the U. S. Navy June 24, 1867, as assistant surgeon; was promoted to the grade of passed assistant surgeon on February 26, 1873; was promoted to surgeon, May 1, 1879; to medical inspector in 1895, and to medical director Sept. 24, 1899, after fourteen years' sea service and eighteen years and two months' land service, and was placed on the retired list with rank of rear admiral, on reaching the age limit of 62 years, on January 31, 1903; but was retained on active duty until April 1, 1903; senior medical officer of the navy yard, New York, during the Spanish-American War; died at the United States Naval Medical School Hospital, Washington, D. C., July 25, aged 69.

Ira Brown, M.D. University of Michigan, Department of Medicine and Surgery, 1858; Vanderbilt University, Medical Department, Nashville, 1876; a member of the Illinois State Medical Society; a veteran of the Civil War; a member of the board of pension examining surgeons at Watseka; died at his home in Milford, Ill., July 24, from heart disease, aged 78.

Luther A. Grizzard, M.D. Medical Department of the University of Nashville, Tenn., 1872; Medical Department of the Tulane University of Louisiana, New Orleans, 1876; a member of the American Medical Association; for a number of years surgeon for the Texas and Pacific Railway Company at Abilene, Texas; died in a sanitarium in Fort Worth, July 27, aged 60.

James Young Crawford, M.D. University of Tennessee, Medical Department, Nashville, 1879; a member of the Tennessee State Medical Association; a Confederate veteran; president of the faculty and professor of clinical dentistry in the University of Tennessee Dental Department; died at his home in Nashville, April 5, from angina pectoris, aged 62.

William Hudson Hopwood, Jr., M.D. Jefferson Medical College, Philadelphia, 1906; a member of the American Medical Association; formerly physician for the Pittsburgh Coal Company at Grindstone, Pa.; died at the home of his mother in Morgantown, W. Va., July 25, from tuberculosis, aged 28.

Julius F. Menestrina, M.D. Washington University, Medical Department, St. Louis, 1890; a member of the American Medical Association; a veteran of the Spanish-American War; formerly of Iron Mountain, Mich.; died at his home in St. Louis, Mo., July 28, from paralysis, aged 43.

Perry W. Welker, M.D. Eclectic Medical Institute, Cincinnati, 1875; health physician of Alliance, Ohio, for more than seventeen years; died suddenly in his stateroom on the steamer City of Mackinac while on his way to Petoskey, Mich., July 27, from heart disease, aged 58.

David Flavel Woods, M.D. University of Pennsylvania, Department of Medicine, 1864; formerly a member of the American Medical Association; a member of the staff of the Presbyterian Hospital, Philadelphia; died at his home in that city, July 28, from angina pectoris, aged 72.

George W. Chisholm, M.D. Detroit (Mich.) College of Medicine, 1904; a member of the Michigan State Medical Society; a prominent practitioner of Pontiac; died at Harper Hospital, Detroit, where he had gone for treatment, July 29, from leukemia, aged 42.

George Murray Stuart, M.D. College of Physicians and Surgeons, Baltimore, 1905; a member of the Medical Society of the State of Pennsylvania; is said to have been shot and killed in his apartments at Pittsburg, Pa., August 1, aged 27.

Charles N. Denison, M.D. Cincinnati College of Medicine and Surgery, 1861; surgeon of the Eighth Illinois Volunteer Infantry during the Civil War; died at his home in Argenta, Ill., July 25, from papilloma of the bladder, aged 74.

William Varner Robertson, M.D. Georgia College of Eclectic Medicine and Surgery, Atlanta, 1887; was found dead in his room at Athens, Ga., July 14, from the effects of an overdose of some narcotic taken accidentally, aged 49.

Delos Walker, M.D. University of Michigan, Department of Medicine and Surgery, 1864; a member of the American Medical Association; died at his home in Oklahoma City, Okla., July 30, from heart disease, aged 78.

Charles R. Strong, M.D. Detroit (Mich.) College of Medicine, 1903; a member of the Michigan State Medical Society; of Detroit; died at the Red Cross Hospital in that city, August 1, following an operation for appendicitis.

Benjamin Dabney, M.D. New Orleans School of Medicine, 1869; a Confederate veteran; formerly of Bonham, Texas; a resident of Dallas for the last two years; died at Fort Worth, July 30, aged 63.

Alexander L. Murphy, M.D. Jenner Medical College, Chicago, 1909; of Chicago; was killed by a Pere Marquette train at Benton Harbor, Mich., July 23, while on his way to Bangor, Mich., aged 36.

Albert E. Shimmel, M.D. University of Michigan, Department of Medicine and Surgery, 1880; formerly of Berlin, Mich.; died at his home in Grand Rapids, Mich., July 30, aged 54.

Virgil W. Blanchard, M.D. University of Vermont, College of Medicine, Burlington, 1859; of New York City; died at his summer home in Middlebury, Vt., July 30, aged 79.

Irvin Baird Brittingham, M.D. University of Louisville (Ky.) Medical Department, 1846; died at the home of his son in Madison, Wis., July 23, from senile debility, aged 85.

Abraham Nestor Fretz, M.D. University of Pennsylvania, Department of Medicine, 1863; a veteran of the Civil War; died at his home in Fleetwood, Pa., July 28, aged 70.

Frederic W. Lilienthal, M.D. University of Berlin, Germany, 1858; of New York City; died at his country estate in the Catskills, July 28, from heart disease, aged 77.

Richard Henry Stone, M.D. College of Physicians and Surgeons, New York City, 1866; died suddenly at Brooklyn, N. Y., July 27, from cerebral hemorrhage, aged 74.

Horace Stanwood Everett, M.D. Harvard Medical School, Boston, 1870; a veteran of the Civil War; died suddenly at his home in Boston, July 26, aged 69.

Frederick Kidder, M.D. College of Physicians and Surgeons, New York City, 1868; died at his home in Afton, Mo., July 26, from cancer of the liver, aged 66.

Benjamin Franklin Emrick, M.D. College of Physicians and Surgeons, Baltimore, 1881; died at his home in Carlisle, Pa., July 26, from heart disease, aged 50.

George Baillie Simpson, M.D. Bellevue Hospital Medical College, New York City, 1887; died at Sheridan, Wyo., July 4, from heart disease, aged 50.

Leander S. Porter, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1880; of Port Clinton, Ohio; died at Dayton, July 26, aged 80.

J. Warren Royer, M.D. University of Pennsylvania, Department of Medicine, 1845; died at his home in Trappe, Pa., July 25, aged 90.

James I. Wright, M.D. Jefferson Medical College, Philadelphia, 1852; died at his home in Philadelphia, July 27, aged 78.

Ellis Holmes Cornish, M.D. Harvard Medical School, Boston, 1867; died at his home in Carver, Mass., July 25, aged 69.

Correspondence

Neurologic Hospitals and Neurologic and Psychiatric Wards in General Hospitals

To the Editor: The timely and instructive article, "The Dependence of Neurology on Internal Medicine: Plea for the Establishment of Neurologic Hospitals and of Neurologic Wards in General Hospitals," by Drs. Joseph Collins and Pearce Bailey of New York (*THE JOURNAL*, July 30, 1910, p. 393), seems worthy of more extended comment than would be feasible in the brief period allotted to discussion at the Section meeting. The contention of the writers that this important branch of medicine has received scant recognition in the past from the philanthropic founders of medical laboratories and institutions may be true, in a general sense. The statement, however, that "in all America there is scarcely a general hospital with neurologic wards worthy of the name, with the exception of a few hospitals and inaccessible city almshouses in which cripples and dotards are crowded together under the care of untrained house staffs without laboratory facilities," seems a little broad. I do not presume to question its approximate accuracy as regards the country at large. From a local (Cincinnati) standpoint, however, it seems only just that we should appreciate more fully the actual advantages that we already possess for caring for neurologic and psychiatric ills as well as for teaching the subjects to the members of our medical classes in the University of Cincinnati. It is worthy of note that, owing to the advanced stand taken by the governing bodies of our Cincinnati Municipal Hospital, for some sixteen years past, a distinct and separate department of neurologic medicine has been in operation, both in the wards and in the clinical amphitheater, where the teaching is open to all medical students in the city at a merely nominal fee. This department comprises some forty beds on an average, bedside teaching to small classes of senior students being also a regular feature. Separate wards are allotted to neurologic patients, the female occupying a portion of a general medical ward. Incidentally, detached rooms have been available for a limited number requiring them; also a closed ward for more disturbed cases. These wards are served by two regular staff members, whose official rank and authority are on a par with those of any other of the staff. These chiefs of staff in the neurologic service alternate with each other in terms of four months each, and the courtesy of allowing either member to retain charge of any important case or cases, after his regular term expires, has always obtained. There have recently been added to the staff two members, with the rank of junior neurologists, whose duty it is to serve in place of or in addition to, the chief of service whenever requested. These junior staff officers also take an important part in the bedside teaching given in the wards regularly to the senior students. A separate intern is allotted to the neurologic service. More important still, this clinical organization is complemented in a most efficient manner by a special laboratory of neuropathology presided over by two salaried members of the university faculty. It may be seen from the above that the strictures of the article referred to, on the prevailing shortcomings for the teaching of neurologic medicine in America, do not apply to the situation in Cincinnati.

A still more important forward step in clinical organization and teaching facilities has just been taken with reference to the department of neurology and psychiatry. Owing to the wisdom and foresight of the efficient and self-sacrificing mem-

bers of the commission for the construction of our new municipal hospital (750 beds) now in course of erection, special provision is made for a separate, isolated and modern neurologic building, to contain also departments for acute psychopathic cases, male and female. Its capacity is to be fifty patients, with provision for expansion as required. This will enable us to avoid the undesirable feature of having neurologic and psychopathic cases, distributed over various parts of a general hospital.

F. W. LANGDON, Cincinnati.

Pharmaceutical Manufacturers and the Great American Fraud

To the Editor: In commenting in your issue of July 30, on Dr. Patek's letter concerning "Pharmaceutical Manufacturers and the Great American Fraud" you say that "the whole history of human progress shows that practically everything we now pronounce necessary to our comfort and material happiness has been brought into being for selfish reasons—that of bringing the inventor or discoverer riches or honor." The sentence might, I think, well be rounded off by adding "or the pleasure of following a congenial vocation." (Recall Bacon's "Happy men whose natures sort with their vocations"). The suggested addition would perhaps justify the toning down of the word "selfish" to "self-regarding."

A very brilliant author of our day somewhere says that all labor done for hire, which would not be done had the laborer an otherwise assured means of livelihood, is prostituted labor; and his epigrammatic phrase seems to reflect the views of authors like John Ruskin and William Morris. True or not, I cannot help thinking that true leaders in pharmacy as in other scientific lines must, after all, have some real love for their vocations, and that this has been a more potent factor in invention and discovery than the desire of "riches or honor."

This love for a vocation is probably intensified by the desire to render service (an altruistic, not selfish or even self-regarding motive); and the essence of our grievance against these great pharmaceutical houses lies in the tendency of their narrow commercial self-seeking to degrade the skilled employee, whose pride and happiness should be in fruitful work and research, to the level of the hireling.

W. R. TYMMS, M.D., Orting, Wash.

Extreme Sensitization From Prophylactic Dose of Diphtheria Antitoxin

To the Editor: Four years ago I administered to a young man 750 units of antidiphtheritic serum as an immunizing dose and within a few moments he was in a serious condition, suffering from dyspnea, general urticaria, rapid pulse, vomiting, etc. He recovered within twelve hours and since that time had been unable to be about horses even for a short time. The emanations from the hairy coat give him severe attacks similar in every way to hay fever, which may become bronchitis secondarily. This patient had no previous personal or family history of asthma or hay fever.

How long is this susceptibility liable to continue, and if he should contract diphtheria, is there any serum that may be used?

L. SIMPSON, Rochester, N. Y.

More New Terms

To the Editor: I want to thank Dr. Henry Freeman Walker for his communication in *THE JOURNAL*, July 2, 1910, page 42, suggesting the word "viroid" as a generic term for the biologic specifics (toxins, bacterial cultures, bacterial products, lymph, serum, etc.) used in active immunization. I have adopted the word; and my own suggestions of "bacterin," "microbin" and "microbion" can now become specific names under the genus "viroid."

I would also call attention to two other terms I am about to introduce, for which there seems to be much need:

pathogen, meaning a material morbid agent of any kind, and *antipathogen*, meaning a pharmakon of any kind which acts against pathogens in general.

S. SOLIS COHEN, Philadelphia.

Correction in Abstract on Bone Lesions

To the Editor: In the abstract of my article on bone lesions in THE JOURNAL, July 30, page 436, the following error was made: "Syphilitic epiphyseal enlargement is bilateral." It should read: "Syphilitic epiphyseal enlargement is unilateral; rachitic epiphyseal enlargement bilateral."

ALEXANDER E. HORWITZ, St. Louis.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

FORMULA FOR OLEUM CINEREUM

To the Editor: Kindly furnish me the formula for preparing oleum cinereum. A. E. CONTER, Apalachicola, Fla.

ANSWER.—A number of formulas for this preparation have been given, differing chiefly in the excipient used. The following is given by the British Pharmaceutical Codex:

Mercury	40.00
Wool fat	10.00
Liquid paraffin, sufficient to produce (by weight).....	100.00

Melt the wool fat, pour into a warm mortar, and, when it is nearly cold but still liquid, add the mercury and triturate until a homogeneous mixture is obtained; then add the liquid paraffin.

DETERMINATION OF FAT IN MILK

To the Editor:—Please state where I can find the method for determining the fat in milk by means of amyl alcohol and hydrochloric acid F. E. CLOUGH, Lead, S. Dak.

ANSWER.—The method is described in Leffmann and Beam's "Food Analysis," pages 205-207 (P. Blakiston's Son & Co., Philadelphia).

The Public Service

Medical Department, U. S. Army

Changes for the week ended Aug. 6, 1910:

Clayton, Jere B., major, will proceed from Vancouver Barracks, Wash., to Camp of Instruction, American Lake, Wash., for duty. Reynolds, F. P., major, granted 10 days' leave of absence. Stallman, George E., dental surgeon, ordered to proceed to the Leon Springs Target and Maneuver Reservation, Tex., for duty during the encampment.

Griswold, W. Church, M. R. C., relieved from duty at Fort Oglethorpe, Ga., and ordered to Philippine Islands, for duty on transport sailing from San Francisco about Nov. 5, 1910.

Brown, Wilmont E., M. R. C., sick leave of absence further extended 3 months.

Williams, Harry B., M. R. C., granted 15 days' leave of absence about Sept. 15, 1910.

Cole, Blase, M. R. C., ordered to proceed from Fort Crook, Neb., to Fort Mackenzie, Wyo., for temporary duty.

Banister, William B., lieutenant col., detailed for duty at the Camp of Instruction, Maneuver Reservation, Sparta, Wis.

Ebert, Rudolph G., lieutenant col., left Headquarters, Dept. of Columbia, Vancouver Barracks, for duty at Camp of Instruction, American Lake, Wash.

Roberts, William M., major, left Camp of Instruction, Gettysburg, Pa., en route to Saratoga, N. Y., and Pimlico, Md., on detached duty.

Clark, John A., leave of absence granted in S. O. No. 143, June 20, 1910, War Department, is extended 15 days.

Winter, Francis A., major, ordered to proceed to New York City, for consultation with the medical supply officer in that city with reference to the purchaser of medical supplies, etc.

Yemans, Herbert W., M. R. C., ordered to repair to this city at the proper time and report in person Aug. 21, 1910, to the Chief of Staff, for temporary duty.

Morse, Charles E., capt., relieved from duty at Schofield Barracks, H. T., and will proceed to San Francisco, and on arrival report by telegraph to The Adjutant General of the Army, for further orders.

Murray, Alexander, capt., on arrival at Seattle, Wash., in compliance with orders heretofore issued, will proceed to Fort Casey, Wash.

Smith, Herbert M., capt., relieved from duty at Fort Casey, Wash., and will proceed to Philadelphia, Pa., for duty as attending surgeon in that city.

Shepherd, John L., leave of absence extended 15 days.

Davis, William T., capt., in addition to his present duties will report in person to Colonel Louis A. LaGarde, Medical Corps, President of the Faculty, Army Medical School, for duty as assistant instructor in ophthalmology and optometry at that school.

Wickline, William A., capt., in addition to his duties with Co. C, Hospital Corps, will report in person not later than Oct. 1, 1910, to Colonel Louis A. LaGarde, President of the Faculty, Army Medical School, for duty as instructor in Hospital Corps and first aid, at that school, relieving Major Charles R. Reynolds, Medical Corps.

Vaughan, Milton, contract surgeon, reported for duty at Fort Logan H. Roots, Ark.

Long, Charles J., dental surgeon, left Fort Adams, R. I., en route to Pine Camp, N. Y.

Pomeroy, William H., contract surgeon, granted 21 days' leave of absence.

Whinnery, J. C., dental surgeon, died at Zamboanga, Mindanao, P. I., July 29, 1910.

Schreiner, E. R., major, left Fort Walla Walla, Wash., for duty at Camp of Instruction, American Lake, Wash.

Truby, Willard F., major, left Fort Worden, Wash., en route to Camp of Instruction, American Lake, Wash.

Van Poole, G. McD., major, and Mount, James R., lieutenant, report for duty at Camp Emory Upton, Sparta, Wis.

Clayton, George R., M. R. C., reports at Camp Bruce E. McCoy, Maneuver Reservation, Sparta, Wis.

Talbot, E. M., capt., and Haverkamp, C. W., lieutenant, report at Camp Bruce E. McCoy, Maneuver Reservation, Sparta, Wis.

Barney, Charles N., major, granted 30 days' leave of absence about Sept. 1, 1910.

Whitmore, W. C., contract surgeon, reported for duty at Fort McKinley, Me.

Burkett, John A., lieutenant, left Fort Riley, Kan., with the 6th Field Artillery, on practice march.

Fox, James S., lieutenant, reported for duty at camp, Leon Springs, Tex.

Medical Corps, U. S. Navy

Changes for the week ended July 30, 1910:

Rhoades, G. C., asst.-surgeon, ordered to duty at the Naval Hospital, Norfolk, Va.

Bloedorn, W. A., asst.-surgeon, ordered to the Navy Yard, Mare Island, Cal.

Downey, J. O., asst.-surgeon, detached from the Naval Hospital, Norfolk, Va., and ordered to duty at the Naval Hospital, Naval Home, Philadelphia.

U. S. Public Health and Marine-Hospital Service

Changes for the week ended Aug. 3, 1910:

Banks, C. E., surgeon, granted 7 days' leave of absence from Aug. 1, 1910.

Wertebaker, W. P., surgeon, directed to proceed to Richmond, Va., on special temporary duty.

Fox, Carroll, P. A., surgeon (on leave), directed to report at the Bureau on special temporary duty.

Korn, W. A., P. A., surgeon, directed to proceed to Point Pleasant, N. J., for the purpose of making examination of keepers and surfmen of the Life-Saving Service.

Sweet, Ernest A., P. A., surgeon, granted 4 days' leave of absence from July 21, 1910, under paragraph 191, Service Regulations.

Spratt, R. D., P. A., surgeon, granted 5 days' leave of absence from July 23, 1910, on account of sickness.

Frost, W. H., P. A., surgeon, directed to proceed to Des. Moines, Iowa, on special temporary duty.

Mullan, E. H., P. A., surgeon, granted 2 days' leave of absence from July 30, 1910, under paragraph 191, Service Regulations.

Preble, Paul, asst.-surgeon, granted 1 month's leave of absence from Aug. 8, 1910.

Kearny, Richard, asst.-surgeon, directed to proceed to San Francisco, and report to the medical officer in command for duty and assignment to quarters. Directed to report to the medical officer in command at Chicago, for temporary duty en route to station.

Draper, Warren F., asst.-surgeon, directed to proceed to Angel Island, Cal., and report to the medical officer in command for duty and assignment to quarters.

Gillespie, Julian M., asst.-surgeon, directed to proceed to Honolulu, Hawaii, and report to the Chief Quarantine Officer for duty. In addition to present duties, directed to report to commanding officer, Revenue Cutter *Thetis* from time to time for temporary duty.

Stiles, C. W., professor, detailed to represent the Service at the meeting of the International Zoologic Congress at Gratz, Austria, Aug. 15-20, 1910.

Blanchard, J. F., acting asst.-surgeon, granted 3 days' leave of absence from July 11, 1910.

Cleaves, F. H., acting asst.-surgeon, granted 3 days' leave of absence from July 28, 1910, under paragraph 210, Service Regulations.

Delo, J. M., acting asst.-surgeon, granted 7 days' leave of absence from July 26, 1910, under paragraph 210, Service Regulations. Granted 7 days' leave of absence from July 24, 1910.

Duffy, Francis, acting asst.-surgeon, granted 6 days' leave of absence from Aug. 3, 1910.

Harkins, F. McD., acting asst.-surgeon, granted 14 days' leave of absence from Aug. 1, 1910.

Hamilton, H. J., acting asst.-surgeon, leave of absence for 4 days from July 19, 1910, amended to read 4 days from July 26, 1910.

Onuf, B., acting asst.-surgeon, granted 7 days' leave of absence from July 22, 1910, under paragraph 210, Service Regulations.

Scott, J. F., acting asst.-surgeon, granted 24 days' leave of absence from June 3, 1910.

Stevenson, J. W., acting asst.-surgeon, granted 30 days' leave of absence from Aug. 3, 1910.

State Boards of Registration

Arkansas Eclectic May Report

Dr. G. A. Hinton, secretary of the Arkansas Eclectic Medical Board, reports the written examination held at Little Rock, May 11-12, 1910. The number of subjects examined in was 12; total number of questions asked, 120; percentage required to pass, 75. The 5 candidates all passed.

College	PASSED	Year Grad.	Per Cent.
Eclectic Medical University Kansas City	(1910)	76.8, 78.7,	81.7, 85.3, 88.7

Michigan May Report

Dr. B. D. Harison, secretary of the Michigan State Board of Registration in Medicine, reports the written examination held at Detroit, May 19-21, 1910. The number of subjects examined in was 14; total number of questions asked, 100; percentage required to pass, 75, and not less than 50 per cent. in any subject. The total number of candidates examined was 35, of whom 33 passed and 2 failed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Detroit College of Medicine	(1909) 79.6; (1910) 75.2, 77.1,	80.6, 80.7, 80.9, 81.5, 81.8, 82, 82.2, 82.9, 83.8, 84.1, 84.5, 85.4, 85.7, 86.1, 86.4, 86.8, 87, 87.4, 87.7, 88.5, 89.1, 89.9, 91, 90.2, 90.5	
Detroit Homeopathic College	(1910)	76.3, 82.5	
University of Michigan, Homeopathic College	(1910)	82.6	
FAILED			
Detroit Homeopathic College	(1910)	66.9	
Detroit College of Medicine	(1910)	68	

Nebraska May Report

Dr. E. Arthur Carr, secretary of the Nebraska State Board of Health, reports the written examination held at Lincoln, May 11-12, 1910. The number of subjects examined in was 13; total number of questions asked, 130; percentage required to pass, 75. The total number of candidates examined was 6, all of whom passed. Twelve candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Ensworth Medical College	(1910) 75, 78.8, 81.8,	85.5, 87.3,	88.8
LICENSED THROUGH RECIPROCITY			
College	Year Grad.	Reciprocity with	
Northwestern Univ. Med. School	(1898) Wis.; (1909)	Illinois	
Rush Medical College	(1881) Minnesota; (1908)	Wisconsin	
College of Phys. and Surg., Chicago	(1903) (1904)	Illinois	
University of Louisville	(1907) W. Virginia		
Central Medical College, St. Joseph	(1898)	Missouri	
Ensworth Medical College	(1908) Kansas; (1890)	Missouri	
Creighton Medical College	(1907)	Iowa	
McGill University, Canada	(1908)	Illinois	

Delaware June Report

Dr. H. W. Briggs, secretary of the Medical Council of Delaware, reports the written examinations held by the Delaware State Medical Society and the Homeopathic Medical Society respectively at Dover and Wilmington, June 21-23, 1910. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. At the examination held by the Delaware State Medical Society, the 6 candidates all passed. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Jefferson Medical College	(1909) 86.7; (1910)	86.8, 91.5	
University of Pennsylvania	(1901) 85.1; (1910)	90.3	
University of Virginia	(1910)	91	

At the examination held by the Homeopathic Medical Society, the 5 candidates all passed.

College	PASSED	Year Grad.	Per Cent.
Atlantic Medical College	(1908) 81.5; (1909) 79, 82.6;	(1910)	84.2, 87.2

Minnesota June Report

Dr. W. S. Fullerton, secretary of the Minnesota State Board of Medical Examiners, reports the written examination held at St. Paul, June 14-17, 1910. The number of subjects examined in was 10; total number of questions asked, 100; percentage required to pass, 75. The total number of candidates examined was 42, of whom 27 passed and 15 failed. Thirteen candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, Chicago	(1910)	80.4

Book Notices

NERVOUS STATES, THEIR NATURE AND CAUSES. By Paul Dubois, M.D., Professor of Neuropathology at the University of Berne. Authorized Translation by Edward G. Richards. Cloth. Price, 75 cents. Pp. 101. New York: Funk & Wagnalls Co., 1910.

This is Dubois's fourth work on the same general subject, namely, the class of diseases that have been usually considered as on the border-land between the organic and the functional nervous disorders, and their psychotherapy. The term "neurasthenia," he holds, has grown in general usage to include a far larger class of nervous symptoms than is altogether proper and is misleading to the extent that it implies that the nerves are at fault. It is not a distinct morbid entity by itself, at least in its usual application, but should be included with psychasthenia, hysteria, hypochondria and simple melancholia in the great class of central neuroses or psychopathic conditions; and these form the subject of this little volume. The author does not fall in with the more modern classification of morbid mental states completely, and especially protests against the materialistic conceptions which would associate these symptoms necessarily with other bodily conditions such as impaired nutrition and intoxications, etc. The psychasthenic individual is an hereditarily weakened one who as a rule belongs to a psychopathic family. There is a degenerative state at base, though not of a kind usually seen with gross physical stigmata. When one recognizes this fact of a primary mental weakness one sees the advantages to be obtained by mental training and therapeutics. The neurasthenic patients are those in whom the symptoms of fatigue, exhaustion and incapacity predominate. In the psychasthenics, in the narrower sense, the obsessions, ties and manias are characteristics, while in the hysterical states there is exaggerated autosuggestibility and a weakened mental synthesis. The hypochondriac and the simple melancholiac differ in their preoccupations. The one is concerned about his state of health, and the other regards exterior circumstances with sadness or his person and conduct with self-accusation. In all of these, there is a fundamental inferiority which is the primary trouble, but this not of the first importance as regards treatment or prognosis. The form the psychoneurosis takes depends on the individual mental peculiarities. The therapeutics of these conditions are not comprised in physical exercises, rest and hypernutrition, except so far as these are demanded by the physical condition, but are more largely in the cultivation of moral ideas and self-control. The patient should be taught the harmfulness of indulging in worry and fear, or of cultivating egoism. The task is the same, in short, as the education of normal people and is possible even in the uneducated so far as the combating of these nervous states is concerned.

LIGHT THERAPEUTICS. A Practical Manual of Phototherapy for the Student and the Practitioner. With Special Reference to the Incandescent Electric-Light Bath. By J. H. Kellogg, M.D., Author of Rational Hydrotherapy, the Art of Massage, etc. Cloth. Price, \$2.50. Pp. 217, with 67 illustrations. Battle Creek, Mich.: The Good Health Publishing Co., 1910.

The title of this book is misleading, because the work is not on phototherapy at all but on thermotherapy as administered by the electric-light bath or reflected electric light. It practically does not consider phototherapy, in the established sense as applied to the method of use of actinic light and as the method was worked out by Finsen and his followers. This misleading title is merely an oversight, however, for the author says in the first sentences of his preface: "The work does not profess to be an exhaustive treatise on the subject of light therapy. It is intended rather to serve as a practical manual for the clinical use of the electric-light bath in its various forms . . ." He considers at length the physiologic and therapeutic effects of radiant heat from intensely luminous sources of high temperature and this part of the work is ingenious and interesting. He makes out a good case for the electric-light bath as a therapeutic measure. He also gives rational explanations for the therapeutic value of the arc-light as used by him for the application to circumscribed areas of radiant heat. The combined use of these measures with hydrotherapy also comes in for full consideration. All this part of the book—which constitutes more than half of it—dealing with the principles and technic of the method is

suggestive and useful. The part directed to the clinical application of the methods in various diseases is less logically worked out and less convincing. Many of the suggestions are a shock to one's pathologic conceptions and lead one to feel that there is danger of the method degenerating into a sanitarium routine. But on the whole the book is a good statement of its subject from the standpoint of an advocate.

THE SURGERY AND PATHOLOGY OF THE THYROID AND PARATHYROID GLANDS. By Albert J. Ochsner, M.D., Professor of Surgery in the Medical Department of the University of Illinois, and Ralph L. Thompson, M.D., Professor of Pathology in the St. Louis University School of Medicine, St. Louis. Cloth. Price, \$6. Pp. 391, with 97 illustrations. St. Louis: C. V. Mosby Company, 1910.

Surgeons, pathologists and internists are alike interested in every addition to our knowledge of goiter and its complications. With the exception of Dock's chapter in Osler's book no treatise has heretofore appeared giving adequate descriptions of the parathyroid glandules. Numerous articles in various languages contained all that was really important in the newer surgery and pathology of goiter until this admirable treatise made its appearance. The latest research in the physiology and pathology of those somewhat mysterious bodies, the parathyroid glandules, is carefully collated in this work and together with the pathology of the thyroid gland this is the work of the junior author (Thompson). The senior author (Ochsner) has contributed the chapters on technic and the whole thyroid gland section except the chapters on pathology. The whole subject of the operative treatment of goiter may be said to belong to the last quarter of the nineteenth century and the first decade of the twentieth. The book also represents much original work, mainly that of Professor Wilson of St. Louis. Post-operative tetany, cachexia thyreopriva, cretinism and hyperthyroidism are each elaborately covered in the latter half of the work. Thirty full page plates minutely illustrate the successive stages of thyroidectomy, and if surgical technic could be learned from half-tone pictures the novice could learn to operate by the use of this work.

LIVING ANATOMY AND PATHOLOGY. The Diagnosis of Diseases in Early Life by the Roentgen Method. By Thomas M. Rotch, M.D., Professor of Pediatrics, Harvard University. Cloth. Price, \$6. Pp. 225, with 303 illustrations. Philadelphia: J. B. Lippincott Co.

The anatomy of the living child, and the diagnosis of disease in early life as it may be studied by the Roentgen ray, are considered by the author in a systematic treatise containing more than 300 illustrations, and combining in the highest degree the art and science of Roentgenology. The distinction between anatomic and chronologic age—a distinction for which we are indebted to the author—is convincingly presented.

The assistance that may be afforded by the rays, not alone in detecting the presence of foreign bodies or anomalies of the osseous system, but in revealing pathologic changes in the soft tissues, more especially of the thoracic or abdominal organs is graphically portrayed by many illustrations. To select one example, the differentiation between dilatation of the heart and pericarditis with effusion can be made from the Roentgenograph by the consideration of the cardiohepatic angle. The book deserves high commendation and should be possessed by every clinician.

ESSENTIALS OF MEDICAL ELECTRICITY AND RADIOGRAPHY. By Edward R. Morton, M.D., Vice-President, Electro-Therapeutical Section, Royal Society of Medicine. Second Edition. Cloth. Price, \$1.75. Pp. 343, with 140 illustrations. Chicago: Chicago Medical Book Co., 1910.

This is an excellent manual. The first 210 pages are given to medical electricity; the last 240 to radiography; radiography is not a part of the volume. The whole work is well done. The apparatus and the physics of both subjects are adequately considered; and the application of the agents to medicine are plainly given, with reasonable conservatism. The book is thoroughly worthy of recommendation.

EMERGENCIES OF GENERAL PRACTICE. By Percy Sargent, M.B., Surgeon to Out-Patients, St. Thomas' Hospital, and Alfred E. Russell, M.D., Physician to Out-Patients, St. Thomas' Hospital. Cloth. Price, \$5.50. Pp. 364, with 91 illustrations. New York: Oxford University Press, 1910.

This is a concise and practical manual, clearly written and well arranged, freely illustrated and of great practical value. The authors confine themselves, very properly and rather unusually, to the subject-matter at hand and do not roam far afield into the domains outside of emergencies.

Miscellany

THE EHRlich REMEDY FOR SYPHILIS*

At a meeting of the Berlin Medical Society, June 22, 1910, W. Wechselmann reported his experiences with Ehrlich and Hata's new remedy for syphilis and discussed the following questions: 1. Is it a specific in syphilis and is it superior to previously known remedies? 2. Does it cure syphilis? 3. Are the dangers of the remedy proportional to the importance of its action.

Wechselmann believes that the most skeptical will admit that the new remedy acts on the symptoms of syphilis in all their infectious forms, with a rapidity and thoroughness which cannot be approached by any other known remedy. He has tested it in eighty cases and states that the action occurred with the certainty of an experiment. Eruptions and ulcerations rapidly heal; in the case of indurated chancre, the surface becomes rapidly clean, but the final healing takes somewhat longer on account of the absorption of the infiltration. It is found that symptoms which do not heal under mercury heal rapidly under the new remedy. The patients begin almost immediately to exhibit an improved general condition and increase rapidly in weight. In one case of visceral syphilis affecting the testicle and also probably the brain, the patient was apparently cured in two weeks with a gain in weight of two pounds. He has observed no relapses, although the period of observation is too short for certainty on this point.

According to his observation the remedy has shown no toxic action. In the case of a patient very much reduced by pernicious anemia, depending on a recent syphilis, an injection of 0.3 gm. (5 grains) temporarily increased the strength, although it was impossible to save the patient's life. No injurious action on the optic nerve has been observed. In infants with hereditary syphilis, which is nearly always fatal, Wechselmann has been able to save two out of five who were treated with this remedy. In the other three the external symptoms disappeared, but death occurred from the affection of the internal organs. Wechselmann prefers the intragluteal injection, its only disadvantage being the severe local pains. (*Berl. Klin. Wchnschr.*, July 4, 1910, p. 1261).

Wechselmann has recently improved the technic by dissolving the remedy in sodium hydroxid solution, adding glacial acetic acid until a precipitate occurs, suspending this in distilled water and carefully neutralizing. In this way the pain is greatly mitigated (*Deutsch. med. Wchnschr.*, July 28, p. 1395).

At the meeting of the Berlin Medical Society, at which Wechselmann's paper was read, L. Michaelis reported several cases, confirming the statements of Wechselmann. At the same meeting Alt reported the results in the treatment of nervous cases. After trial on the higher animals he tried the remedy on fifty syphilitics. His results were very favorable. He reports one case of very severe syphilitic icterus which disappeared in about nine days after the injection of 0.4 gm. The remedy was tried in a number of relatively recent cases of tabes and in six cases he observed not only a marked retrogression of the subjective symptoms but also an improvement in the objective symptoms and in the general condition. He reports favorable results in the treatment of epilepsy depending on syphilitic taint. He finds that the excretion of the arsenic takes a somewhat longer time than was formerly supposed. He has seen cases in which arsenic was still being excreted ten to twelve days after the injection.

Neisser writes to the *Deutsche medizinische Wochenschrift* (June 30, 1910, p. 1212), that it is yet too early to give a definite opinion, as an insufficient number of cases have been treated, but he says that it can be affirmed with certainty that the new remedy exerts a remarkable, even surprising action on the spirochete, as well as on the syphilitic products themselves. Spirochetes disappear in very many cases after from twenty-four to forty-eight hours from primary lesions and con-

dylomata in which they were abundantly present before administration. It produces a local reaction in papules and other cutaneous lesions. As to the syphilitic processes, so rapid a retrogression of primary lesions, papular syphilides and especially ulcers can be observed so as to leave no doubt regarding the specific character of the remedy. He reports a prompt relief of symptoms in a case of brain syphilis. He has obtained a reversal of the seroreaction in only about 10 per cent., but thinks that this may be due to the use of too small doses. The cases in which this reversal of reaction occurred were those which came under treatment soon after infection. It does not always prevent the progress of the disease, however, even when applied in cases of primary lesion before the seroreaction is positive. It seems, however, when given to apes, to delay and mitigate the primary lesion. He thinks that the remedy will be especially useful in cases in which mercury treatment has failed or cannot be applied. He advises private practitioners to delay the use of the remedy until present uncertainties regarding dosage and the number and repetition of the injections are settled.

Schreiber and Hoppe (*München. med. Wchnschr.*, July 5, 1910, p. 1430), report their experience in a number of cases. They resort to the intravenous injection and in the treatment of 30 cases found no unpleasant side-effect. The rise of temperature which has been observed in cases in which intramuscular injections were made did not occur in the intravenous injection. They noted no injurious effect on the kidneys nor on the digestive organs. In two cases they noted a scarlatina-like eruption which came on ten days after the injection and lasted three days.

In fifty-two cases they found that the Wassermann reaction became negative in 92.3 per cent. This occurred in the earliest case, four days, and in the latest, seventy days after the injection, but in most cases within fourteen days. They noticed a leukocytosis in most cases. No toxic symptoms were observed by them and they call attention to the fact that the highest dose which they had employed was 0.0096 gm. per kilo, and the toxic dose as shown by animal experimentation is 0.15 gr. per kilo, so that the doses in present use could be considerably increased. For this reason they have increased the dosage from 0.3 to 0.7 gm. They concluded that the remedy has an absolute specific action in syphilis which is manifest after a single injection. They consider it as contraindicated in severe diseases of the circulatory organs, the kidneys and the eyes.

H. Loeb (*München. med. Wchnschr.*, July 26, 1910, p. 1580), reports thirty-five cases with very favorable results. He saw no toxic symptoms and noted in cases in which roseola was present an intensifying eruption (Herxheimer's reaction). One patient relapsed; but he attributed this to an insufficient dose (0.14). The Wassermann reaction was only slightly affected in his cases. But he thinks the time is too short in which to form an opinion.

G. Treupel reports nine cases which confirm the reports of other observers (*Deutsch. med. Wchnschr.*, July 28, 1910, p. 1393).

Fischer and J. Hoppe have investigated the excretion of arsenic (*München. med. Wchnschr.*, July 19, 1910, p. 1531). In the use of this remedy they found that the excretion in paralytics required from twelve to fourteen days and the amount excreted in the urine was quite variable. In the case of epileptics with healthy kidneys, the excretion of arsenic lasted only about three days. This is true also of ordinary syphilitics. Generally the excretion was completed sooner after the intravenous injection than after the intramuscular injection. They found that the preparation was not absorbed to any great extent by the rectum, but a considerable amount of arsenic was excreted in the stool after intramuscular or intravenous injections. The excretion per rectum continued longer than by the kidneys. They found also that after an intramuscular injection a considerable amount of arsenic remained for a long time in the muscular tissues. Thus in cases which came to autopsy they found arsenic in the gluteal muscles, in one case after fourteen days and in another after thirty-six days.

* This subject is discussed editorially in this issue and also in the Berlin Budapest letters, pages 609 and 610.

Gall-Stones Containing Typhoid Bacilli.—An instance of the formation of cholesterol gall-stones containing typhoid bacilli within sixty-eight days of the onset of typhoid fever is reported by Hertz and Adams (*Proc. Roy. Soc. Med.*, May, 1910). A woman, aged 24, had always been constipated, her bowels never moving more than twice a week, and then only with the aid of purgatives. For three years or over, since the birth of her child, she had occasionally suffered from a dull aching pain in the epigastrium, which began immediately after food and was occasionally relieved by vomiting. It was not sufficiently serious to cause her to take medical advice. She had not had typhoid previously. The typhoid fever ran a typical course from Dec. 2, 1909, to Jan. 14, 1910, when she had a relapse, with fever and rash, which lasted until January 24. February 1 she complained for the first time of pain in the epigastrium and back, and vomited. The gall-bladder was found to be enlarged and slightly tender. There was no jaundice or pyrexia. The pain persisted and attacks of bilious vomiting occurred from time to time. On February 18 the temperature rose to 99.4 F. and the patient was sent to the hospital and from the symptoms suppurative cholecystitis was diagnosed. The patient was operated on the same evening. The gall-bladder was distended, tense and adherent to surrounding structures. It was opened and 4 ounces of clear fluid escaped and half an ounce of pus was evacuated. Twenty-five faceted gall-stones were removed from the gall-bladder, which consisted of slightly pigmented cholesterol of the usual hardness. The clear fluid and pus both contained pure culture of *B. typhosus*. The same organism was isolated from the center of some of the gall-stones. As this was the patient's first attack of typhoid fever, and the *B. typhosus* was found in the center of the gall-stones, it is clear that they must have been formed between the onset of the typhoid fever on December 12 and the operation February 18, a period of sixty-eight days.

Recognition of the Individual by Hemolytic Methods.—Dr. C. Todd and R. G. White reported to the Royal Society, June 16 (*Nature*, June 23), experiments which they sum up as follows: "1. The immunization of the ox with the red blood corpuscles of other oxen gives rise to the formation of a hemolytic amboceptor in the blood of the immunized animals. 2. The amboceptor so formed is an isolysin, but not an autolysin. 3. The race of the animal appears to have very little influence on the resulting hemolysins. 4. The serum of an animal so treated acts very differently on the red blood corpuscles of different individual oxen. 5. The serums of different individuals similarly immunized differ from one another in their action on the corpuscles of different individuals. 6. If the serum of a single immunized animal be 'exhausted' with excess of the corpuscles of one other individual, the serum loses its power of hemolyzing the corpuscles of this individual, while retaining the power of hemolyzing the corpuscles of many, but not all, other individuals. 7. If, however, a polyvalent serum be made by mixing the serum of a large number of immunized animals, and this serum is exhausted with the corpuscles of any one individual, the serum entirely loses its power of hemolyzing the corpuscles of this individual, but remains strongly hemolytic for all other individuals not closely related to the individual the corpuscles of which were employed for the exhaustion of the serum. (N. B.—It is possible that exceptions may be found.) 8. The red blood corpuscles of any individual are thus characterized by a definite individuality of their own, and can be distinguished from those of any other individual of the same species."

The Influence of the Operation of Resection of the Kidney on Function.—The experimental work which forms the basis of this preliminary report by Cunningham (*Bull. VI, Med. School of Harvard University*, April, 1910) was suggested by an operation on a young woman with but a single kidney, which contained calculi. The kidney was exposed and split in Brödel's line and three calculi of medium size removed from the kidney and another the size of a pea from the ureter through the pelvis of the kidney. The ureter was then proved to be patent. The incision in the pelvis was closed with fine silk and in the substance with mattress sutures of catgut. Following operation about 1 ounce of bloody urine

was removed by catheter. The patient was catheterized one hour later and then every half-hour subsequently, but no urine was obtained from the bladder until eight and one-half hours after operation. At that time a little more than 1 dram of slightly bloody urine was obtained. The amount of urine then increased gradually to the normal amount. The question to be determined by Cunningham's experiments was: Does a kidney which is subjected to an operation, temporarily cease functioning, (a) when the wound is closed by sutures, (b) when the kidney wound is drained, by a rubber tube or by gauze. Rabbits were used in the experiments and methylene blue was injected into the stomach hypodermically. The findings and conclusions were as follows: The rabbit normally urinates about every three hours. After a left-sided nephrectomy, urine was not voided for from ten to eighteen hours, except in one instance, when a blue urine was voided in from four to six hours. After resecting a portion of the remaining kidney, opening into the renal pelvis and closing the wound entirely, urination did not take place for between thirty-eight and forty-three hours, and in one instance between forty-three and forty-four hours. After resecting a portion of the kidney and draining it with a rubber tube through the loin, urine was secreted in every animal before eight hours, and in most between six and seven. After resecting a portion of the kidney and draining it with gauze through the loin, urine was secreted in all the animals between six and seven hours except in one which showed a blue fluid between four and five hours. The urine drained through the loin and also through the ureter into the bladder. Cunningham says that it will thus be seen that following the operation of kidney resection and closing the wound in the kidney entirely, there results a temporary arrest of the kidney function; that performing the same operation and draining the kidney pelvis, not closing the kidney wound entirely, does not cause a suppression of kidney function, in the same degree at least; that when the kidney pelvis is drained by a rubber tube, the drainage through the loin is freer than when the gauze is employed. He is not able to explain any of the facts stated.

The Nervous Child.—It is a lamentable and disquieting fact that nervousness in childhood is increasing, says A. Roos (*Layman's Med. Jour.*, May, 1910). Nervous children are present in all classes of society, in the country as well as in the cities. Even shortly after birth may be observed a peculiar smile, distortion of features, spasmodic rolling of the eyeballs and incoordinate movements, the primary cause of which may be some trivial disturbance of digestion indicating a state of nervous morbidity. Convulsions are common a few months later during dentition; also sleeplessness, irritability and periods of crying and screaming without adequate cause. In pneumonia the nervous symptoms may be of sufficient intensity to mask the symptoms of the primary disease and they may resemble meningitis. Two distinct types of nervous temperament are recognized, psychic hyperesthesia and psychic hypesthesia. To these should be added a third condition characterized by periods of depression and dullness alternating with intervals of excitability. In the class of the first type are the children of delicate, spare build, mentally too far advanced for their age. The children of the apathetic class are less frequent, are usually well nourished, with an abundance of adipose tissue, phlegmatic and indifferent to external stimuli. Those of the changeable temperament are most frequently observed. They are apt to be effusive in their fondness for others at one time, and at another without cause indifferent, offensive and quarrelsome. They are enthusiastic in their play or school work, or again apathetic, indolent and discouraged. In the nervous child the resistance to external influences is diminished so that trivial causes, such as sudden excitement, a thunderstorm or the sight of a wound or drop of blood produces a psychic effect influencing the entire nervous system and the vasomotor system, producing pallor or vertigo, faintness and unconsciousness, or the influences may be transmitted to the motor nerves and we see the child uninterruptedly in motion. Standing, walking, sitting positions rapidly succeed each other, the fingers, hands and feet are never at

rest; nervous twitching of the facial muscles is not uncommon: the internal organs are not infrequently affected and there are palpitation, cramp-like pains in the region of the bladder and a desire to evacuate this organ or the bowels. Frequent and prolonged headaches are common. Nervousness in both parents is transmitted to offspring, but nervousness on the paternal side alone less frequently, unless it amounts to a neurosis. Nervousness on the maternal side is more frequently transmitted. Indifference, disrespect, contempt, etc., on the part of the parents, or alcoholism of the latter, will have effect on the children of such a union. Acquired causes of nervousness may be pathologic, as concussion or contusion of the brain from accident, acute congestion of the brain from infectious diseases, sunstroke, etc., and acute encephalitis or meningitis. In addition, are reflex causes, such as eruption of teeth, worms, constipation and localized pains, and constitutional diseases, such as anemia, albuminuria, diabetes, rickets, auto-intoxication, suppurative conditions, etc. Physiologic causes may be attributed to deficiencies in connection with the bringing up of the child, and may refer to the physical condition, the mental and moral state. Impressions on the extraordinarily sensitive brain of the first and second stages of childhood may become permanent and indelible, and should therefore be correct. Improper literature should be strictly avoided. Evening dancing parties, the theater, etc., for the very young are harmful, because they interfere with the regularity of habit and sleep. Remorse, injustice, jealousy, anger, are powerful causes of excitability. A systematized, regular method of living is of extreme importance, and should be begun immediately after birth and strictly adhered to. Errors in mental education are made not only in school, but more frequently in the home. Few parents devote themselves to the education of their children by the application of thorough discipline and a definite system or method. Some parents are authoritative and unnecessarily rigorous, avoiding explanations; others are indifferent, indolent and excessively indulgent. The child is without guide, is conscious of its power and the effect of its tears, is a veritable tyrant and abuses its power in order to obtain increased privilege. The inevitable consequence of this kind of training is pronounced nervousness. A sane method must be adopted in bringing up children and such a system must be adhered to.

Typhoid and the Milk-Supply of Washington Hospitals.—The Washington Milk Conference of 1907 decided that the limit of safety for milk to be consumed raw required that it should contain not more than 100,000 bacteria to the centimeter, and that all milk containing more should be pasteurized (*Wash. Med. Ann.*, ix, No. 1). The high mortality from typhoid fever in the hospitals of the District of Columbia and its possible connection with the milk supply led the Hygienic Laboratory of the U. S. M.-H. Service to collect samples of milk as found in different localities in Washington, with the result that the minimum count showed 340,000 bacteria per cm., running from that to 2, 3, 4, 5, 10, 15, 50 and up to 111 million per centimeter, and among these samples were some from a half dozen prominent hospitals and asylums. The average mortality from typhoid fever in the United States is 10 per cent., but the mortality in the Washington hospitals sometimes reaches the appalling rate of 16, 18, 20 and even 25 per cent., and in only one was it as low as 7 per cent. The danger from raw or improperly pasteurized cream is even greater than from improperly pasteurized milk, as it is found that the cream contains about 60 per cent. of the bacteria, although constituting but one-twentieth of the whole milk. Those who are studying the problem believe that nothing short of proper pasteurization will ever accomplish a reduction in the death-rate, and they urge municipal control over pasteurization plants so that the people may not be lured into a false sense of security by the mere word "pasteurized," since commercial pasteurization is often done so imperfectly as to be worse than none at all. Because milk offers a good supply of nourishment bacteria increase at an amazing rate, but the rate of increase is approximately seventy times greater at 60 F. than at 50 F., and this explains the high mortality in the summer time of infants fed on raw or improperly pasteurized milk.

Medicolegal

Liability for Malpractice in Case of Inexplicable Burn in Administering Static Electricity

The Supreme Court of Minnesota says, in *Frisk vs. Cannon & Balcome* (126 N. W. R., 67), that the plaintiff charged the defendants, as partners engaged in the practice of medicine, with having negligently treated her with static electricity, to her injury, but the trial court was justified in concluding that the defendants were not partners, and that the defendant Cannon was not liable for the alleged negligence of the defendant Balcome.

The plaintiff alleges that she was placed on an insulated platform connected with the electrical machine, a conical cap was put above and in front of her head, and static electricity was caused to be discharged by the machine through the cap on her head; that the defendant then left the room, and no attendant was present. After the lapse of eight or ten minutes the plaintiff screamed. The defendant immediately entered the room, and discovered that her head was smoking. A large portion of the top and sides of her head was seriously burned. Five thousand dollars damages were claimed, and a verdict of \$1,200 was returned in the plaintiff's favor, against the defendant Balcome, judgment for which is affirmed.

The statement by the court is very brief, but much that physicians will be interested in knowing about the case is contained in the dissenting opinion of Justice Jaggard. He says that the defendant called a number of well-known experts of the highest character. The effect of their testimony was: The amperage or the quantity of electricity generated by the machine in question was infinitesimal. It figured at some one-millionth of an ampere; but the electro-motive force was large. The effect resembled shooting a piece of elder-down from a gun. There was great force, but the missile was so slight in character that it could do no harm. No case had ever been known of injury to a person by a static machine, nor was one known in the literature of the profession. The occurrence was "unique in experience," "a perfect mystery, contrary to all laws of physics." It could not be accounted for by any action of the static machine. A physician who had been using one in his practice daily since 1885, and had given perhaps 100,000 treatments, gave similar testimony. Another physician, with 17 years' experience in the use of the machine, testified that he knew of nothing which could have produced this injury by this machine, and he knew of nothing which could have prevented it.

The way in which the conical cap, described as an inverted crown or sunflower, was placed near the plaintiff's head, the one suggested explanation of how the accident happened, was not shown to have been its cause. According to the plaintiff, that cap was placed within two or three inches from her head, instead of six or eight inches away, as at other times. The decrease in distance tended to increase the strength of the current communicated to the patient's head; but it had never been known to produce the effect here complained of before the accident. It was shown by uncontradicted and unimpeached testimony that the force of the charge or amount of electricity used or turned on the plaintiff in its usual operation would have been absolutely harmless, however the cap had been adjusted; that if the cap had been placed immediately on top of her head, it might have produced unpleasant sensations, but according to all known experience would not have injured the plaintiff. "Good practice requires that it should just clear the head; that is all." The patient could perceive the cone in front of her, so that, if there had been a spark, she would have seen it, but did not see it. Moreover, it is the universal experience that there might have been a spark without possible harm. It was also to be noted that it was the back of the head which was burned.

Nor was the absence of any assistant in the room with the plaintiff shown to have been a material factor. How such person, if present, could have prevented the harm, did not appear. If he had, for example, turned off the electricity

which operated the machine, its wheels would have revolved for some time from momentum. Nor was it suggested how any interposition could have been effective to have stopped the passage of the current, which the plaintiff said took more time than a second, but which must have been practically instantaneous. It appeared that the presence of a physician or an assistant was not required by good medical practice, nor that there was any reasonable anticipation of harm which suggested it. Neither the facts in the record nor any conjecture reasonably founded thereon tended to show that the failure of the physician to give the plaintiff any directions concerning the use of the machine, or to be present in person or by representative, was the proximate cause of the harm complained of.

The defendant had a right to rely on the presumption of the uniformity of the operation of natural forces. He was not bound to anticipate that a certain exceptional phenomenon, beyond the range of invariable and extensive experience, would happen. This accident was like a flash from a clear sky.

For such reasons Justice Jaggard says that he is compelled to conclude that the plaintiff suffered from the results of a physical force partially known and in some measure unknown, whose particular potentiality for harm could not have been reasonably foreseen, and for which the defendant was not responsible.

But the Supreme Court holds that the plaintiff made out a prima facie case of negligence. It says that her only expert testified that, if the cap were brought close to the head and there was volume enough, there would be a continuous spark and harm would result. His testimony to the effect that the distance the cap was placed from the plaintiff's head would determine whether a burn was likely to occur, together with the testimony of the plaintiff that it was not adjusted as on former occasions, and also the conduct of the defendant in leaving the plaintiff in the room unattended, while the machine was working, for the space of ten minutes, during which time the burn occurred, in connection with the other evidence in the case, was sufficient to take the question of the defendant's negligence to the jury, with the result already stated.

7. Treatment of Varicose Veins.—The procedure followed by Pool is as follows: At the time of the dressing, three times a week, the patient is made to lie on the back on the examining table with both legs elevated almost to a right angle and supported against the wall; the patient lies in this position for about 15 minutes. For the first few treatments massage is administered, stroking the limb toward the trunk. Before lowering the legs they are cleansed and dressed in an appropriate manner by strapping, medicinal applications, etc., and a muslin bandage is applied tightly and smoothly. The patient is instructed to resume this position three times a

day for fifteen minutes each time, and at other times if the bandage feels too tight. Pool says that no complaints have been made concerning the discomfort of the bandage and very few as to the tightness of the bandage. All the patients have expressed themselves from the outset as very much pleased with the results, stating that the legs are not only more comfortable, but show a more marked disposition to heal than by other methods. By this method the engorgement of the veins and lymphatics is prevented, and the edema diminished, as is evidenced by rapid diminution in the diameter of the legs after a brief period of treatment. Occlusion of the deep veins contraindicates the tight bandaging.

Pool emphasizes that the method is intended to supplement and not as a substitute for other procedures. It will simply expedite the response of the tissues to curative agents. Appropriate local treatment must be as assiduously pursued as when this method is not followed. The only departure from the usual routine here suggested is the detail of elevation which seems to enhance the effect of the bandaging.

13. Prophylaxis in Psychiatry.—Summing up his conclusions of the future of psychiatry as a factor in the field of social service, Wright says that cooperative education is the key-stone in the arch of prophylaxis. Cooperation which is not merely abstract, in the nature of annual conferences and reports between one profession and another, but direct personal cooperation, such as is now obtainable between the worker in the charitable relief agencies and the physicians and nurses of hospital dispensaries; cooperation with the schools, the social settlements, charitable relief organizations, the courts and the clergy; education in the schools, from public platforms, through the direction of the public library and the press, and more directly in the clinic and the home in matters pertaining to mental hygiene, by those properly qualified in psychopathology.

If this can be accomplished, statistics of the etiology of insanity will not, as now, he says, represent much labor lost, except as resulting in a vast array of ambiguous uncorrelated statements, but more and more efficient labor with a clearer insight; while the benefit to the unfortunate patient and his relatives, which after all is the chief thing to consider, will be immeasurable by any statistical method.

14. Anesthesia in the Aged.—After having used a combined partial scopolamin anesthesia with local anesthesia, using 0.1 per cent. cocaine for six years, Gleason now uses partial scopolamin anesthesia, combined with local sterile water infiltration anesthesia in operating on the aged. He says that the aim should be to produce complete sensory paralysis of the part. Satisfactory results in the matter of producing regional anesthesia are dependent on the technic, and in order to become proficient in this, practice and experience are essential. The operator must be familiar with the anatomy of the parts, especially of the sensory nerves. The injections may be thus made with accuracy where they will be most beneficial and without unnecessary insertions of the needle. To gain control of the field it is necessary to block the nerves by depositing the sterile water around and in close proximity to them. Gleason places emphasis on the necessity of producing the condition of absolute nerve block in order to obtain the best results. Considerable fluid and some force must therefore be used.

The degree of anesthesia produced is governed by the accuracy with which the location of the nerves is determined,

the amount of fluid injected, and the degree of force used. It is in this particular that experience and the resulting judgment which is developed is most valuable. Gleason is convinced that by this method the management of surgical diseases in old people may be made comparatively safe, the mortality much reduced, and seemingly inoperable cases made operable and curable.

18. Nephritis Without Albumen.—That gross and severe lesions of the kidney may exist without albumen being present in the urine, or at least without being discernible by the methods ordinarily used in hospital and office work, is the conclusion at which Howland has arrived. From April 1 to December, 1909, he examined 550 specimens of urine. All urine was centrifuged from three to six minutes in an electric centrifuge giving from 1,000 to 1,800 revolutions to the minute. The sediment was removed by a thoroughly clean small pipette, the finger being held over the end and the point lowered until just over the sediment. The finger was then removed from the outer end sufficiently to allow only a small amount of the sediment to be admitted into the pipette, which was then held there by replacing the finger on the outer end. The sediment was placed on a glass slide and spread out over at least one square inch of surface, the slide being then placed under the microscope and held in position on a moving stage. The sediment was then examined under low power with closed diaphragm, and by means of the moving stage a systematic search of the whole field made; Heller's nitric acid test was used in all cases, with filtered urine, and the result tested before a dark background. As a rule, only morning specimens were used. The average amount was from 6 to 8 ounces, and the specimens were not over twelve hours old.

In many of the cases recorded numerous examinations were made and several methods employed. In cases in the acute stages which showed casts the urine was examined every few days, and in chronic conditions once or twice a week. Howland reports 21 cases which illustrate the presence of nephritis without the presence of albumen. All cases which showed granular in addition to hyalin casts are included, but not those cases which showed one or two hyalin casts only. Casts without albumen were found in a large proportion of those patients who were suffering from conditions such as appendicitis, typhoid, peritonitis, gangrene and evulsion of the scalp. In these patients the toxins incident to these troubles doubtless had a pathologic effect on the kidney without producing albumen.

19. Drugs in Practice.—Tyrode cites a few instances to show what can be done by the proper use of drugs. He praises the work done by the Council on Pharmacy and Chemistry, directing attention to its various publications which he urges practitioners of medicine to read. Speaking of new drugs, he says that there is no doubt that this flood of new drugs and combinations has its chief value in increasing the income of the manufacturers rather than advancing the art of therapeutics, for it is not so much a large number of a certain class of medicinal agents which we need, but rather a better understanding of the already known ones. It is true that we must place great hopes in the development of synthetic pharmacology, i. e., the building up of new compounds having certain desirable actions but not possessing certain undesirable ones at the same time. For instance, of the hundreds of newer coal tars as antipyretics and analgesics none have really surpassed some of the older compounds. The newer artificial morphin derivatives have not proved themselves as valuable as morphin and codein. The new bromid substitutes are not equal to potassium bromid.

Chloral still remains the most powerful hypnotic of the fatty acid series and is far superior in activity to any of its substitutes, and frequently not much more dangerous.

A physician who pretends to treat patients should know how to mix drugs in a prescription himself without the suggestions of a patent medicine house, and furthermore, if he desires any ready-made mixtures, he can find all sorts in the United States Pharmacopeia and National Formulary. Much better results at lower cost will be obtained by using home-made beef juice, scraped beef, etc., instead of the patented beef-preparations; likewise arrow-root, cornstarch, blanc-mange, barley-water, tapioca and rice will advantageously fill the place of the patented cereals, as the malted milks and infant foods. Instead of the patented fats, as various emulsions of cod-liver oil, and some particular frauds claiming to contain the active principles of cod-liver oil without the disagreeable fat, far better results may be reached by the employment of cream, buttermilk and olive oil. If one wishes to use alcoholic preparations, the ordinary good brands of wine, beer, ales and spirits will not only equal but excel any patent wines or malt extracts. The farcical use of uric acid solvents, as patented lithia waters and certain piperazin compounds, can be advantageously substituted by the use of large amounts of ordinary water with simple alkaline salts, as potassium citrate and sodium bicarbonate.

22. Tuberculin at the Sharon Sanatorium.—Tuberculin has been used at the Sharon Sanatorium for diagnostic purposes for 8 years, and as a therapeutic measure for 5 years. One hundred and nineteen patients have been tested by it, and 36 have had it as treatment. 44 have been discharged less than a year ago from the sanatorium and these are not considered in Griffin's report, which is intended to be, in part, a record of the present condition of those patients who have received tuberculin. This leaves, then, to be considered, 83 patients who have been tested and 28 who have been treated. Of those tested, 4 are known to have died, but only one of these died of tuberculosis. Griffin says that it is wise and safe to test all patients with signs in the chest who do not present tubercle bacilli in the sputa, using for this test the submucous method. If disease is found, a cure should be begun and the patient should be taught sanatorium methods. Neither does there seem any harm in using as high a dose as 10 mgm., since, when this dose is worked up to gradually, it does not cause a severe reaction. And, further, if a less dose were taken as the limit of use, some cases would fail to be detected which might need sanatorium treatment.

Treatment with tuberculin was begun rather experimentally on 3 patients who were moderately advanced and who had apparently come to a standstill in their improvement under general hygienic conditions. They seemed peculiarly fitted, therefore, to test the value of some treatment in addition to the regular sanatorium régime. These first three cases were so encouraging that each year more have been given tuberculin treatment, until at present there are ten having it, or nearly half the capacity of the sanatorium. In all cases either old tuberculin or bouillon filtrate have been used.

Of the 28 patients who have received the treatment, 6 have died. Two of these were far advanced at the start and were given injections at their own request. Three others who were not favorable cases were given tuberculin on the chance that it might help when all probability of help by ordinary means seemed futile. The sixth patient did well and left the sanatorium in good condition, dying about a year later of a sudden hemoptysis. Two others of the 28 returned to a poor environment, contrary to advice, and are not doing well. Two more have relapsed in spite of care. These last cases may improve in the future, and from what can be learned they are certainly not hopelessly sick. This leaves 18 who are in good condition. From his experience at Sharon Griffin feels that tuberculin when carefully given is not likely to do any harm and that it frequently is of great benefit, affecting a cure in some patients that would not be expected to do well under ordinary methods of treatment, and, finally, that no patients with frank tuberculosis should be denied the privilege of tuberculin treatment if they desire to have it.

27. **Prolapse of Urethra.**—A woman, aged 54, married some 20 years, never pregnant, gave a history of painful micturition and presence of protruding mass of indefinite induration at urethra. On examination a provisional diagnosis of a primary carcinoma of the urethra was made from the symptoms and the feel of the prolapsed mass. The family history of the patient was very good and positively free from tuberculosis and carcinoma. A wide removal of the mass was made and microscopic examination showed it to be an angioma. For a period of one week catheterization had to be practiced. The subsequent history after one week was that the patient had good control, urination was painless, and from appearance, recovery was complete.

33. **Cutaneous Trichophytin Reaction.**—Patients suffering with trichophytia profunda respond to subcutaneous injections of culture filtrates of different strains of trichophyton, called trichophytin, with local and general reaction. The local reaction occurring at the point of injection gives rise to inflammation and infiltration. Besides this reaction at the point of injection, but less constantly and less pronounced, there occurs another local reaction in the diseased area. The general reaction consists of malaise, headache, muscular pains, rise of temperature, etc. Superficial cases of trichophytia do not give any reaction under the usual conditions. The analogy of this reaction with the tuberculin reaction in cases of tuberculosis is very striking. The trichophytin reaction is just as specific as the tuberculin reaction in the sense that it is not observed in healthy individuals or in patients suffering with diseases not due to an infection with hyphomycetes belonging to the trichophyton group. It is of interest that trichophytin prepared from different types of trichophyton derived from clinically different cases act alike, so that this reaction cannot be utilized for the differentiation of various trichophyton infections.

The total number vaccinated by Amberg with trichophytin was 131. Of these, 107 were vaccinated simultaneously with tuberculin, bouillon treated exactly like the tuberculin but without any bacteria, and trichophytin. The bouillon vaccinations were made in order to see whether it might give reaction by itself. In one case only, a doubtful reaction occurred, and this was at the point where the bouillon was inoculated. All the other cases showed a completely negative result. Besides these 107, ten were vaccinated with tuberculin and trichophytin, one with bouillon and trichophytin, and 13 only with trichophytin. The tuberculin vaccinations did not give any result not noted before. Amberg concludes

from his observations that there exists a far-reaching analogy between the cutaneous trichophytin reaction and the cutaneous tuberculin reaction. Both indicate that the organism is the seat of a definite infection or that it has passed through such infection. Both may persist for a long time after the active disease has come to rest, indicating that the infection has left the organism in a state of altered reactivity—allergy. Under certain conditions both may be of diagnostic value, but since the reaction persists for a long time after the infection has passed, the negative reaction may be of greater value, excluding the existence of a specific infection. The analogy of the trichophytin reaction with the tuberculin reaction is not only limited to the obvious clinical manifestations, but, as in the tuberculin reaction, it can be shown that with uniform concentration of antibody the intensity of the reaction is dependent on the concentration of the trichophytin. A tentative explanation of the halo formation is offered by Amberg, based on a rapidly renewed formation of antibody stimulated probably by the entrance of a small amount of allergen into the general circulation.

34. **Latent Life of Arteries.**—Carrel has found that when a segment of artery, killed by heat, formalin or glycerin, is transplanted, it undergoes a rapid degeneration. Its muscle fibers disappear while the tissue of the host reacts by building a new wall of connective tissue. When the transplanted vessel has been preserved in a condition of latent life, no degeneration of the wall occurs, or the wall undergoes only partial degeneration. The muscle fibers can keep their normal appearance, even for a long time after operation. It is, therefore, demonstrated that arteries can be preserved outside of the body in a condition of unmanifested actual life. The best method of preservation consists of placing the vessels, immersed in petrolatum, in an ice-box, the temperature of which is slightly above the freezing point. From a surgical standpoint, the transplantation of preserved vessels can be used with some safety. When the arteries were kept in defibrinated blood or petrolatum and in cold storage, the proportion of positive results was 75 and 80 per cent., and this can probably be increased.

35. **Studies in Edema.**—In order to determine further the factors which influence absorption from the peritoneal cavity, Fleisher and Loeb studied the absorption in nephrectomized animals and in animals injected with uranium nitrate, 20 and 72 hours after injection. In the experiments recorded the influence of the osmotic pressure of the blood on absorption of fluid from the peritoneal cavity becomes apparent. Nephrectomy, removal of the adrenals, and other operations increase the osmotic pressure of the cavity. On the other hand, ether narcosis, at the period at which the authors tested its influence, causes neither an increase of osmotic pressure of the blood nor an increase in the absorption of fluid from the peritoneal cavity. The increased osmotic pressure and increased absorption of fluid in nephrectomized animals is to a great extent not a specific effect of the removal of the kidneys, but approximately the same conditions can be observed after incisions of the skin and muscles. After poisoning with uranium nitrate and in cases of peritonitis, complicating factors come into play, and under such conditions the absorption from the peritoneal cavity is not increased, notwithstanding the higher osmotic pressure of the blood.

In conditions in which the osmotic pressure of the blood is very high before the injection of sodium chlorid solution into the peritoneal cavity, nephrectomized rabbits or rabbits injected with uranium nitrate 3 days previously, adrenalin causes no increase, or only a very slight one, in the absorption of peritoneal fluid. On the other hand, one day after the injection of the uranium nitrate the osmotic pressure of the blood is only slightly increased before the injection of the sodium chlorid solution into the peritoneal cavity, and here adrenalin causes a marked increase in absorption of fluid from the peritoneal cavity. In animals injected with uranium nitrate the retention of sodium chlorid and other osmotically active substances in the blood is not entirely due to interference with the functions of the kidney. This retention may be explained either by an inability of the

tissues to bind the sodium chlorid and other osmotically active substances or to a diminished permeability of the blood vessels for such substances.

While in nephrectomized animals the elimination of sodium chlorid from the peritoneal cavity and also from the blood is increased, in animals injected with uranium nitrate such an elimination is diminished. This increase in the sodium chlorid content of the peritoneal fluid in animals treated with uranium nitrate is accompanied by a decrease in the diffusion of other osmotically active substances into the peritoneal cavity. While in nephrectomized animals and in animals injected with uranium nitrate one day previously, adrenalin causes a diminution of the fluid retained in the blood-vessels similar to the diminution noted in normal animals, adrenalin no longer exerts such an effort at a later stage of the uranium nitrate poisoning. At this period after the administration of uranium nitrate, the retention of fluid in the blood vessels is apparently equal in experiments with and without the injection of adrenalin, and following the absorption of fluid from the peritoneal cavity, the retention of fluid in the blood vessels in the uranium nitrate animals is increased comparatively to a greater extent than in normal animals.

36. *Id.*—In this paper Fleisher and Loeb record their observations on the influence of caffein on absorption from the peritoneal cavity and the influence of diuresis in edema. In normal animals the injection of caffein slightly diminishes the absorption of fluid from the peritoneal cavity, in spite of the fact that the amount of fluid and sodium chlorid eliminated through the kidneys is markedly increased. The lessened absorption of fluid is due to a slight lowering of the osmotic pressure of the blood. In nephrectomized animals caffein increases the absorption of fluid from the peritoneal cavity; the increase in absorption is greater in nephrectomized animals which received caffein than in nephrectomized animals which did not receive this substance, and it is due to additive increase in the osmotic pressure of the blood. In animals injected with uranium nitrate three days previously, caffein diminishes the absorption of fluid from the peritoneal cavity, notwithstanding the high osmotic pressure of the blood observed in such animals.

At the time of the conclusion of the absorption experiments, the amount of fluid retained in the vessels was found to be diminished in each series in which caffein was used. Only in certain cases can this be due to the increased amount of fluid leaving the blood vessels through the kidneys; in other cases it can only be due to a movement of water from the blood vessels into the tissues caused by the injection of caffein. In normal animals, in nephrectomized animals and in animals in which an operation not directly affecting the kidneys had been performed, caffein caused an absolute and relative increase in the elimination of sodium chlorid from the peritoneal fluid, as a result of which the remaining peritoneal fluid shows a lessened content of sodium chlorid. Caffein causes also a decrease in the sodium chlorid content of the blood.

Summarizing all experiments in which they studied the absorption from the peritoneal cavity, Fleisher and Loeb state that changes in the osmotic pressure of the blood represent the principal factor in explaining the variations in the rate of absorption of fluid from the peritoneal cavity. There exists no direct relation between an increase in the rate of absorption of fluid from the peritoneal cavity and an increase in the amount of urine secreted. If it should be found that even at a period following the injection of caffein, later than that at which we have studied the absorption, a rise of the osmotic pressure of the blood does not appear, then we may state that the diminution in the amount of edema in the body cavities resulting from the administration of caffein is entirely due to an inhibition of the production of edema and not to an increased absorption of fluid from the serous body cavities.

37. **Fuchsin Bodies.**—The material used by Brown included over 200 distinct specimens representing nearly all the organs of the body and a great variety of pathologic conditions as well as some normal tissues. This material was selected

partly at random and partly from lesions in which Brown felt sure of finding fuchsin bodies. He believes that he is justified in assuming that the fuchsin body represents a type of body subject to wide variations in morphology and in staining reaction. Though more frequently associated with plasma cells than with any other cell type, these bodies may and do occur in a great variety of cells, and also within blood vessels; some of these bodies are true hyalin thrombi, while others are due to autolytic changes in the red blood corpuscles. Fuchsin bodies are most numerous in granulation tissue and lymphoid areas. In the former, they follow closely the distribution of capillaries and show a parallel with the changes in the extravascular and intravascular red blood corpuscles. The number and type of fuchsin bodies in tissues can be influenced by methods of fixation, the number of typical bodies being inversely proportional to the rapidity and degree of fixation of the red blood cells. The type of body found after the best fixation is not, as a rule, what is considered the typical form, but an irregular fragmentary type or the fuchsinophilic granular form. The identity in staining reaction, the constant association with changes in red blood corpuscles, the relation to distribution of capillaries in granulation tissues, the occurrence in hemorrhagic lesions associated with pigment, the intravascular occurrence, and, finally, the close relation to pigment deposits, all indicate conclusively that fuchsin bodies arise from red blood corpuscles.

No theory of origin from plasma cells, or other granular cells, offers an adequate explanation for the origin of fuchsin bodies, nor can any theory prove adequate which does not take into account the red blood corpuscles. The peculiar association of plasma cells with fuchsin bodies and hemosiderin seems explainable on the assumption that the plasma cell in such instances is the active factor in a metabolic process, the fuchsin body representing a stage in the metabolism of hemoglobin by an intracellular enzyme, and hemosiderin, one of the products of the process.

39. **Neurocytoma or Neuroblastoma.**—Wright calls attention to a group of tumors the nature of which he believes has hitherto escaped general recognition. These tumors are rich in cells which may vary much in size and shape. They may be perverted by connective tissue by which the cells are arranged in more or less definite alveoli. Blood vessels accompanied by connective tissue are also present. The essential cells of the tumor are considered to be more or less undifferentiated nerve cells or neurocytes or neuroblasts, and hence the names neurocytoma and neuroblastoma. Wright cites briefly 12 cases seen by him or recorded in the literature.

 65 *Friedreich's Ataxia. W. G. Spiller, Philadelphia.

64. Deafness Due to Lesions in the Brain.—Owing to the course of the acoustic tract, Starr says it is to be expected that lesions in the pons Varolii and in the tegmentum of the crura cerebri which affect the lemniscus should produce deafness, but cases of this kind appear to be extremely rare. He reports a case, one of an apoplectic attack characterized by alternating paralysis of motion and of sensation, by dysarthria, and by total deafness in both ears. The patient, whose arteries had become markedly atheromatous, from a long-continued abuse of alcohol, had a slight attack of right hemiplegia and aphasia in the year 1900, when 42 years old. The symptoms rapidly subsided and as the attack was not attended by loss of consciousness, it seemed probable that it was due to a thrombosis in a small vessel, leaving a focus of sclerosis of small extent and without permanent effects.

In June, 1901, a second apoplectic attack, however, occurred, more severe in character, the permanent symptoms of which remained until her death in 1909. In this attack she became unconscious and remained so for two days, after which time it was apparent that the right side of her face and the left arm and leg were paralyzed. Sensation in the right side of the face was markedly impaired to touch, temperature and pain, and the same loss of sensation was apparent in the left arm and left leg and on the left side of the body as high as the collar. In addition to the alternating paralysis and anesthesia, there was a very marked loss of muscular sense in all four extremities, being more marked on the left side. The patient was unable to swallow and choked at any attempt, so that she was fed for a month with difficulty. She was entirely incapable of pronouncing words distinctly and as time went on, this difficulty increased, being intensified by her total deafness. From the day of the attack until her death she was totally deaf in both ears. The deafness was complete for all sounds, high or low, and there was no bone conduction of sound. There was no disease of the ears. This condition was present for eight years. There was apparently no return of hearing whatever.

80. Biologic Variations.—Clinical evidence, says McCready, would seem to warrant the assumption that there are a large number of children retarded in their mental development on account of insufficient activity caused by biologic variations of the special centers making up the zone of language. These children are likely to be considered feeble-minded and they may eventually become so unless their condition is recognized and proper treatment instituted.

102. Chronic Stomach Troubles.—Winslow emphasizes the following points: 1. That chronic so-called stomach troubles are mostly not stomach troubles; 2, that the importance of laboratory findings of the gastric contents in so-called stomach troubles is greatly exaggerated; 3, that a careful clinical history gives the clue in most cases and is the chief aid in diagnosis of so-called stomach troubles; 4, that, excluding the neuroses, the so-called chronic stomach troubles resolve themselves commonly into chronic gall-bladder disease, chronic appendicitis, duodenal ulcer, gastric ulcer and cancer. There is probably about 25 per cent. of chronic stomach troubles in which no one can make a positive diagnosis. The chief object will then be to decide whether the case warrants surgical exploration. If exploration of the abdominal and pelvic organs were done in every case where the abdomen was opened for chronic trouble, there would be less operating on the same patient and less neurosis.

124. Chorio-epithelioma.—Henry reports 3 cases. Operation was performed in each case, but owing to advanced disease, one of the patients died. In this case examination showed a uterus only slightly enlarged, and in about normal position. Situated on the anterior and posterior wall of the vault of the vagina were two vascular soft tumors about the size of a pigeon's egg, so located that the opinion was expressed that one was transplanted from the other. The woman was anemic from loss of blood which had been going on for two or three weeks. The primary tumor was found in the body of the uterus, not so large as the two secondary growths. The second patient had a small tumor the size of a large hazelnut in the uterine wall, apparently of malignant structure. The microscope showed it to be chorio-epithelioma. The mucous membrane and the rest of the body appeared to be normal. The patient made a good recovery. The third patient was supposed to be 3 months pregnant when hemorrhage began and she was apparently threatened with a miscarriage. On account of her hemorrhages, albumin in the urine, and rapid heart, the consultant advised emptying of the uterus. On examination he found a delicate young woman with a pulse of 140, temperature 101, but on putting his hands on the abdomen he found the uterus extending to the umbilicus, vagina filled with blood clots and os patulous. On thoroughly dilating and passing in a Thomas spoon a great quantity of cysts began to come away. Eight weeks later her pulse became rapid again, temperature had gone up to 101 and 102, but a blood count did not show the septic factor and was accordingly ruled out. On curetting the uterus to clear up the diagnosis, such a furious hemorrhage set in that Henry tamponed the uterus. The curetting showed a malignant condition and three days later, after direct transfusion, the uterus was rapidly removed. The tumor had penetrated the walls of the uterus and was just starting into the broad ligament. A year later the woman was in perfect health.

139. Difference between Systolic Pressure in Arm and Leg.—The results which Hare has obtained in making comparative studies of the blood pressure in the arm and leg of cases of aortic regurgitation have not only confirmed Hill's conclusions that in aortic regurgitation there is a remarkable difference in systolic pressure found in the arm and leg, but have given greater variations than he records, and Hare is prepared to agree with Hill that this extraordinary difference between the systolic pressure in the arm and leg is a pathognomonic sign of aortic incompetence, as it is not present in other valvular lesions. In one of Hare's cases this method of reaching a diagnosis of aortic regurgitation proved most helpful because the ordinary characteristic symptoms of this disease were not well marked. The pulse was somewhat triphammer in character but not sufficiently so to be typical. Auscultation revealed a double murmur, very feeble in character, and equally well heard in the mitral and aortic areas. There was a systolic murmur transmitted into the carotid, but the diastolic murmur could not be separated from that of mitral stenosis or Flint's murmur. In this case it was found that the systolic pressure in the arms was 160 and in the legs 260. On taking the patient where there was a good light, Quincke's capillary pulse was found in the skin and in the lips. In another case the arm pressure was 170; the leg pressure 265.

2. Leukocytes in Infection and Immunity.—The observations made by Andrewes on the bone marrow of the rabbit in staphylococcal infections are in complete accord with those of Roger and Josué and of Muir. He employed the intravenous route of infection, and when death occurred rapidly, in 40 hours or less, from acute septicemia, he found no leukoblastic reaction in the marrow, but rather a depletion of the tissue in respect of its neutrophile cells. These are the cases which show a circulatory leukopenia as the end approaches. But in every case in which life has been prolonged for four days or more, he found a neutrophile leukoblastic reaction in the marrow; these are the patients who show during life a persistent, if variable, polynuclear leukocytosis, and after death, local foci of tissue infection. He further found that the longer the animal survives the more pronounced is the neutrophile transformation of the marrow.

From these facts, Andrewes draws two conclusions. It would seem that the "plant" for the production of polynuclear leukocytes present in normal marrow, though it may suffice for a high transitory leukocytosis, is quite inadequate for the maintenance of high leukocytosis. In presence of a grave pyogenic infection steps are at once taken to increase the plant necessary to keep up a due supply. In spite of this the patient or the animal may die, but it is permissible to assume that in every case showing a sustained circulatory leukocytosis this marrow reaction is present and that when, as is commonly the case, recovery occurs, the reaction has been part, and, he thinks, a very important part, of the machinery by which the body has overcome the infection. The prognostic value of the leukocyte count in such human diseases as pneumonia rests on a definite anatomic basis.

The second conclusion is that of the vast importance of the polynuclear leukocyte in the bodily struggle against invasion by the pyogenic cocci. The immediate steps which seem to be taken to provide an increased supply of these cells in presence of such invasion, and the disastrous results which seem to attend failure of the supply, can bear only one interpretation, according to Andrewes. If, in any given bacterial infection, a sustained polynuclear leukocytosis is found during life, and, after death, a neutrophile leukoblastic reaction in the bone marrow, we are fairly entitled to conclude that the defense of the body against the microbe in question, rests largely, perhaps entirely, with the polynuclear leukocytosis, and is probably phagocytic in essence. In a rabbit which had been three times treated intravenously with a vaccine of *Streptococcus fecalis*, and which died for no apparent reason, Andrewes found 315,000 neutrophile cells per cubic millimeter of bone marrow, but in another animal killed after similar treatment the number was only 138,000, and in a third, which died much wasted, the number was 128,100. In an animal killed after two intravenous inoculations with *Micrococcus citreus agilis*, Andrewes found no leukoblastic reaction in the marrow; the neutrophile count was 134,000 per cubic millimeter. He says that the body reacts differently according to the species of bacterium by which it is invaded or against which it is vaccinated.

The clinical facts in relation to different human infective diseases have long suggested this and the more closely the cytologic changes in the blood and the humoral properties of the serum are studied, the more apparent is the fact that the body has several means of defense. There is a great difference between these infections and those due to the pyogenic cocci as regards the changes seen in the blood and in the bone marrow. In experimental rabbits treated with intravenous doses of living and dead colon bacilli, Gärtner's bacillus and *B. typhosus*, Andrewes regularly noted a polynuclear leukocytosis, often a high one, following the anaphylactic leukopenia, but it is a transient affair, and he believes it to be a reaction following the leukopenia, rather than a serious attempt at phagocytic defense. He has never found a leukoblastic reaction in the marrow of animals thus treated. The pyogenic cocci, the members of the colon bacillus group, and the microbes of tubercle and probably also of syphilis, are examples of micro-organisms against which the body seems to defend itself in very different fashion. So far as the polynuclear leukocytes are concerned, Andrewes concludes that these cells are of fundamental importance in defense against the pyogenic cocci, of merely secondary importance in the case of the colon group, while in tubercle and syphilis they seem to play almost no part at all.

9. A United Medical Profession.—Medical education is discussed briefly by Shaw. He suggests the creation by the British Medical Association of a section dealing with the subject of medical education. Here, he says, there would meet together on equal grounds, as members of the profession, the teachers and the taught, and much might be done toward forming a sound opinion on certain principles of education. The taught might bring home to the teachers that teaching is an art that might well be learnt by those who propose to practice it. The medical teachers' faith in examination as a means of education might in such open discussion be advantageously shaken.

13. The Country Practitioner of To-day.—Puckle pleads for hearty and unselfish cooperation and combination within our ranks as being the only way of successfully confronting the numerous forces attacking us from without. It is useless, he says, for a few to make a stand against encroachment on their right to a place in the sun at the hands of private patients and public bodies, if within their ranks are to be found those who are willing to accept what others with the true interests of the profession at heart indignantly reject. It is no use presenting a bold front to the common foe if you know that you will probably be stabbed in the back by a so-called friend.

We must live, and, when all is said, the laborer is worthy of his hire. Surely, therefore, in the common interest, it should be possible for neighboring colleagues to put a stop to underselling, by mutually agreeing on a scale of charges suitable to each district, and based on occupation and mileage, and loyally keeping to it. That is one line our combination might take, and though more or less a sordid detail, is none the less an important one. That "union is strength" has been true for all ages, and now that the struggle for existence is daily growing fiercer has passed beyond the region of platitudes.

- 31 Diptera of the Congo-Zambesi Watershed. A. Y. Massey.

30. Blackwater Fever.—In practically all the cases Foran examined, small active coccus-like bodies or "blood dust" were to be seen. They varied much in number, but in two cases, both young native children, with anemia and enlargement of the spleen, they were present in such extraordinary numbers that, on looking at the fresh film, the plasma seemed to be seething with them. On staining, however, there was no trace of them. Foran found this parasite in many young native children and in a fair number of Europeans. Of the former, some were suffering or had suffered from symptoms closely resembling mild attacks of blackwater; and of the latter, two had had blackwater, and the others were suffering from anemia and irregular fever. Some of the cases appeared to be purely infections; others had undoubtedly a malarial element. In a few young children with acute symptoms, he found remarkably rich infections, 1 in 3 or 1 in 4 of the

red cells invaded. In others, and in the Europeans, the parasite appeared to be latent, with only a few free forms and still fewer intracorpuscular.

Foran suggests that the parasite described is a piroplasma, and that it is the cause of blackwater fever. The intracorpuscular forms closely resemble malaria, and may have been confounded with it. During the attacks of blackwater fever in Europeans the parasites may not appear in the peripheral circulation at all; they may congregate and multiply chiefly in the organs, and there invade the red cells, and these invaded cells, being, perhaps, especially susceptible, may get broken down before reaching the peripheral capillaries. The absence of pigment would render it difficult to demonstrate the presence of the parasite in sections.

33 Responsibilities in the Prevention of Inherited Syphilis. S. Sheil.
34 *The Rotunda Hospital. E. H. Tweedy, B. A. H. Solomons and J. R. Freeland.

34. Rotunda Hospital.—During the year 1908-09 there were 2,369 admissions in the maternity wards of the Rotunda Hospital and 2,045 deliveries, which is 15 less than the previous year. Tweedy's cases of eclampsia up to date number 73. This is not only the largest series of cases published by one observer in Ireland, but surpasses the combined number of his two predecessors. A close inspection of former reports will, according to Tweedy, demonstrate the fact, which has been repeatedly noted by other observers, that the incidence of eclampsia is apparently in the nature of an epidemic. This fact is worthy of more than a passing notice, for it is possible that it may serve as a clue to the recognition of the cause of the disease.

In respect to contracted pelves, Tweedy enters a plea for their estimation in inches rather than centimeters. Thus, if starting with $4\frac{1}{2}$ inches as the normal conjugate, one can divide the different contractions into 5 degrees, the first four separated from each other by half inch measurements, the fifth degree comprising all pelves with a true conjugate less than $2\frac{1}{4}$ inches. This presupposes that a simple flat pelvis is being dealt with; in the presence of general contraction the condition must be considered worse by half an inch. Tweedy also pleads for precision in pelvic measurement in carrying out scientific methods of treatment; that this precision can be obtained only by Skutsch's pelvimeter, the use of which requires considerable practice; that treatment based on the known size of the pelvis will yield better results than that obtained by any other single method. Of other methods, the most important is Professor Muller's, which is of immense utility, but not of universal application. It often fails in obese women, or when the child lies in the third or fourth position with the head extended.

He no longer considers it justifiable in a well appointed hospital to induce premature labor or to perform prophylactic version as a treatment for contraction without complication. These women may be allowed to fall into labor and deliver themselves naturally, provided that the narrowing is not greater than the first or second degree. Delivery by forceps or by enlargement of pelvis should not be delayed when once material or infantile symptoms of distress have appeared, and for these a careful and continuous watch should be kept. In contractions of the third degree the patient's powers should not be wasted by a prolonged second stage, for an enlarging operation will nearly always be necessary for delivery. In the fourth degree of contraction Cesarean section, intraperitoneal or extraperitoneal, is the operation of necessity, if the child is alive, while craniotomy with cleidotomy if necessary, can be relied on for delivery, if the child is dead. In the fifth degree, whether the child is dead or alive, it is best extracted by Cesarean section. Two Cesarean sections were performed during the year.

Labor was induced 11 times—for a dead child 4 times, for albuminuria and edema once, for hydramnios once, for myoma once, and for ante-partum hemorrhage, once. There remain three cases in which labor was induced at full term because of fetal death on former occasions from unexplained causes

when labor occurred spontaneously. Live children resulted in these cases. There were 34 cases of post-partum hemorrhage, during the year; 22 cases occurred before the placenta left. In 12 of these the placenta was expressed directly from the uterus; in the other 10 a portion or all of the placenta was adherent necessitating manual removal—three times, of pieces of placenta left after expression; seven times of the whole placenta. Six of the 34 cases followed operative delivery, necessitating an anesthetic. The treatment was as follows: Intrauterine douche followed by a gauze plug, 11 cases; intrauterine douche, 8 cases; repair by catheterization, expression of placenta, massage, manual control, and the administration of ergotin.

37 *Evolution of the Stump of the Cervix after Subtotal Hysterectomy. (Evolution du moignon cervical après l'hystérectomie subtotale.) M. Mériel.

37. Fate of the Stump after Subtotal Hysterectomy.—Mériel reviews the various mishaps liable to occur after incomplete hysterectomy. Leucorrhea is the rule for a week or a month afterward, and it may persist to such an extent as to require removal of the stump of the cervix later. The glands in the cervix develop excessive secretion under the influence of the operative traumatism; in rabbits Burkhardt found the stump transformed into a cystic tumor at the end of a few months. This excessive secretion in the cervical glands might be avoided by making the amputation lower down, close to the vagina, thus leaving fewer glands to secrete. The records show further that in from 3 to 6 per cent. of the cases the stumps develop malignant degeneration. Richelot compiled 22 cases in 1905 and the list is much longer now. The cervix may have already contained a cancerous growth at the time of the operation or the supposed fibroma may have been a sarcoma. For these and other reasons Mériel advocates total hysterectomy, not leaving any stump, and presents statistics to show that the mortality of the two techniques does not materially differ. The danger of infectious complications by way of the vagina can be obviated, he thinks, by swabbing the vagina with dilute tincture of iodine and curetting the cervix the night before the operation to remove accumulations of mucus. French surgeons in general, he says, seem to be discarding the subtotal for total hysterectomy more and more.

43 *Indications for Various Operative Methods with Hypertrophy of the Prostate. Bensa.
44 *Case of Rapid Postoperative Recurrences of Traumatic Urethral Stricture. M. Palazzoli.

38. Bismuth Paste in Urology.—This communication from the Paris Necker hospital relates the application of Beck's bismuth paste in 10 cases of fistula resulting from removal of a tuberculous kidney and another of a fistula with a simple pyonephrosis with concretions. Nine articles on the use of the bismuth paste have been published in France. The paste used was a mixture of 10 parts bismuth with 10 parts each of paraffin and lanolin and 20 parts of vaselin. The amount injected was only from 5 to 10 or 12 c.c. except in a single case. In other points Beck's technique was followed and although such striking results as he has reported were never observed, yet on the whole the verdict is favorable. A cure was attained in some cases in which the process had proved rebellious to all other measures. The suppuration is materially reduced by the paste which renders it unnecessary to change the dressing as often as otherwise.

41. **Non-Gonorrheal Urethritis.**—Motz classifies non-gonorrheal urethritis aside from the venereal form as of traumatic, clinical or spontaneous origin or consecutive to descending infection of kidney or bladder, and he then discusses the therapeutic indications for these five types when the trouble is recent. Some do better with mild disinfectants, while the primary venereal urethritis may require stronger measures and the urethritis due to the presence in the urine of certain irritating salts or toxins demands general treatment before instituting local measures.

43. **Indications for Operative Treatment of Hypertrophy of the Prostate.**—Bensa determines by cystoscopy (1) the shape of the hypertrophy, (2) its consistency by palpation through the rectum and its nature in general by the hematuria and the various secretions, and (3) the state of the general health, especially that of the lungs, heart and kidneys, testing for urea, albumin and sugar. Total transvesical prostatectomy he reserves for fibroadenomatous hypertrophy of the lateral lobes in younger and only slightly infected patients, and it is done in two sittings with a temporarily infected patient. Partial transvesical prostatectomy is applicable for a pedunculated middle lobe. Perineal prostatectomy is preferable when there is suppuration—on account of the facility of drainage, and possibly for the lower hypertrophied lobes. The Bottini operation may be applied for soft hypertrophy of the lateral lobes, which it is difficult or impossible to enucleate, for "bar" hypertrophy of the middle lobe and stenosis of the neck of the bladder; also when the patient refuses an abdominal operation or is too weak for any other technic. This Bottini operation removes the part of the prostate obstructing the posterior urethra and neck of the bladder. The results are certain, permitting almost without any danger the removal of the obstacle to urination. Suprapubic cystotomy is advised in the hemorrhagic forms or when there is infection of long standing; it should be supplemented by deep cauterization of the protruding lobes or bands in the neck of the bladder. In some cases the cystotomy alone is all that is indicated to relieve and soothe the bladder by diverting the urine, and this treatment thus forms the last resort when all the ramifications of the urinary apparatus are distended and infected.

44. **Recurring Stricture.**—Palazzoli emphasizes the fact that a stricture cannot be regarded as cured until the underlying cause has been definitely removed. In the case reported the inflammation was the result of injury from a concrement and the stricture constantly recurred after dilatation. This persisting inflammation can generally be detected and cured only by palpation and massage over a large bougie in the urethra, possibly supplemented with electrolysis.

- 46 Mechanism of Action of Secretory Stimulants Introduced by Way of the Rectum in Dogs with Pawlow Fistula. Wasserthal.
- 47 Evacuation from the Stomach of Cold Mineral Waters Ingested Fasting. A. Monsseaux.

45. **Enteritis Due to the *Trichocephalus Dispar*.**—Cade and Garin's patients were between 25 and 40 years old and the syndrome varied in each case but the diarrheic form with invisible hemorrhages was most common, persisting for months and years. In some cases periods of constipation intervened, and in some the tenesmus and colics simulated dysentery, or the false membranes in the stools suggested mucomembranous colitis. The trichocephalus locates by preference in the right iliac fossa, and the symptoms may include a spasm of the bowel suggesting a pathologic induration in this part of the intestine. In some of the patients gastric symptoms predominated, the clinical picture simulating then nervous or neurasthenic dyspepsia. Headache, dizziness and weakness were constant symptoms and a temperature at times up to 38 C. or still higher for a few days was sometimes noted. The discovery of occult blood in the stool and of eggs of the helminth are important aids in differentiating, as also the lingering nature of the symptoms and their flaring up especially in summer. In one of the cases cited the diagnosis had

long been tuberculous enteritis but the occult blood and the trichocephalus in the stool and the improvement under thymol confirmed the assumption of helminthiasis. They gave thymol in 15 grain doses three or four times a day for three or four days, following with a saline purgative, the patient abstaining in the meanwhile from alcohol, wine and oil. This course was repeated after an interval of a few days. It does not always abolish the helminths entirely, even with several courses, but great improvement in the condition was always manifest and no untoward by-effects were noted in any instance.

- 49 Anaphylaxis for Cow's Milk in Infants. (Anaphylaxie pour le lait de vache chez les nourrissons.) Barbier.
- 50 *Inflammatory Nature of Stenosis Ascribed to Muscular Hypertrophy of the Pylorus in Infants. E. Weill and Péhu.
- 51 *Epidemic of Whooping-Cough with Gastro-intestinal Complications. (Considérations sur quelques complications d'une épidémie de coqueluche et sa disparition brusque à la suite d'une cause météorologique.) N. B. Nicoletopoulos.

48. **The Heart in Acute Articular Rheumatism in Children.**—Nobécourt advises keeping a child in bed and giving sodium salicylate even in the very mildest cases of acute rheumatism, enforcing bed rest with especial insistence with any signs of complications on the part of the heart; if the myocardium is involved even the slightest movement may bring on syncope. He also advises an exclusive milk diet or milk or vegetable diet, keeping the bowel function regular with enemas and laxatives and applying sinapisms and dry or wet cupping over the heart if there is much pain. In this case and also if the myocardium shows signs of weakness, he keeps cold wet compresses or an ice bag over the heart. The majority of physicians keep up the salicylate even with myocardium trouble; the drug does not seem to have the depressing action that used to be feared from it, and it may have a favorable action on the serosa. Weill tried subcutaneous injections of sodium salicylate in parenchymatous myocarditis but without apparent effect. On account of the analogies between the virus of the disease and lactic acid, alkalines have been given in treatment by some and they do not seem to do harm, to say the least. After subsidence of the acute phase, the patient should be kept under supervision and exercise, arsenic, iron and iodids and a course of mineral waters ordered as indicated. He cites a number of cases from his experience to show the various types of heart trouble liable to be encountered, including two cases of functional mitral insufficiency and some cases in which the endocarditis, pericarditis or myocarditis occurred with attenuated rheumatism, even without joint lesions or fever. P. Weill has encountered cases of actual visceral rheumatism with no joint symptoms.

50. **Inflammatory Nature of Stenosis of the Pylorus in Newly-Born Infants.**—Weill and Péhu present data to sustain the assertion that the stenosis is sometimes merely the result of a hyperplasia of the pylorus musculature secondary to an inflammatory process in the stomach. The inflammation may be of greater or less extent and intensity which explains the variability of the symptoms. The gastritis may be clinically cured by medical measures and these should be given a thorough trial and time to act before considering operative treatment.

51. **Whooping-Cough.**—This communication from Greece states that during an epidemic of whooping-cough gastro-intestinal symptoms suggesting typhoid were common and proved fatal in a number of cases. The epidemic was in summer but a sudden change in the weather, bringing a cold northeaster, seemed to blow the whole epidemic away. The local doctors, meeting two days later, all had wonderful tales to tell of the great efficacy of the special drug which each had happened to be prescribing for his little whooping-cough patients the day the weather turned. On comparing notes, however, they came to the conclusion that some general factor must have been responsible for the benefit derived on that and the following day in all the cases from the various drugs that had been used. And this factor seemed to have been the sudden change in the weather.

53 *The Dog as Typhoid-Bacilli Carrier. (Le chien, porteur de bacilles d'Eberth.) J. Courmont.
54 *Differential Radiodiagnosis of Gall-stones and Urinary Calculi. A. Bécère.

53. Dogs as Typhoid-Bacilli Carriers.—Courmont found that 10 of the 12 dogs tested eliminated typhoid bacilli regularly in their stool for four or five days after eating a single meal of food experimentally contaminated with typhoid bacilli. The bacilli seemed merely to pass through the dog's body without causing lesions or symptoms, but it is evident that during the five days following ingestion of typhoid material the dog is liable to be a dangerous bacillus carrier. In the two cases with negative findings in the stool the bacilli proved afterward to have been derived from cases of Malta fever.

54. Radiodiagnosis of Gall-Stones and Urinary Concrements.—In the case reported by Bécère the symptoms indicated kidney stone and radioscopy showed a large concrement in the right side. Its shadow was 40 mm. in diameter when the tube was placed above the patient but the shadow was only 28 mm. in diameter when the tube was placed beneath, the patient's position and the distance of the tube the same for each exposure. This difference in the size of the diameter with the upward and downward exposures indicated that the stone must have been much nearer the front than the back of the body, suggesting that it was in the gall-bladder rather than in the kidney, although there had been no signs of anything wrong with the biliary apparatus. The hematuria was still unexplained until the tube was applied to the left side also, when a small kidney stone was discovered.

- 55 *Malarial Hemoglobinuric Fever Should Not be Treated with Quinin. (Quelques mots sur l'étiologie et la pathogénie de la fièvre bilieuse hémosphérinurique; devons-nous la traiter par la quinine?) J. Cardamatis.

Nos. 9-10, pp. 21-24

- 56 Influenza and Dengue. (Grippe et fièvre dengue.) P. N. Divaris.

55. Should Quinin be Given in Hemoglobinuric Fever?—Cardamatis has been collecting the experiences of physicians throughout Greece in regard to hemoglobinuric fever and its treatment with quinin and states that in 2,481 cases, including 55 from his own practice, the mortality was 24.42 per cent. in the 1,347 cases in which treatment was with quinin, but only 7.32 per cent. of the patients died in the 1,134 cases in which no quinin was given. This list includes the experiences of 105 Greek practitioners, in as many different foci of malaria, and the conclusions from the total statistics confirm what Cardamatis has been teaching since 1893, namely, that complete abstention from quinin is necessary in treatment of bilious hemoglobinuric fever. The hemoglobinuria is stated to have followed eating green beans or their flowers in a number of cases, and Kouzis has isolated from fresh beans a special ferment which he calls "cyamose," but Cardamatis thinks that the trouble is more likely to be explained by some minute mushroom growth on the raw beans, the mushrooms containing some poisonous element. One of the Greek physicians reported a case brought on apparently by emotional stress, in another by the odor of resin, drinking a glass of an infusion of quassia or decoction of absinthe, or, in one child of 8, by eating a very large number of figs. In Gliompres' case fatal hemoglobinuria came on after eating a dish of snails. Blood from the hemoglobinuric patients failed to show any evidence of a special hemolytic action or a destructive action on the malarial parasite.

July 3, No. 27, pp. 1325-1376

- 59 *Intestinal Dyspepsia. A. Cade. Commenced in No. 26.

57. Absorption of Ultraviolet Rays by Impurities in Air, Etc.—Bordier reports extensive research on the absorption of the chemical rays by various substances, organic fluids, transparent solutions, etc., and draws some practical conclusions. The crystalline lens and cornea become fluorescent under the action of the rays, showing transformation of energy, and this transformation of energy cannot occur, he believes, without some physiologic transformation which in time may become pathologic. He advises careful exclusion of the ultraviolet rays in all sources of illumination, kerosene lamps and incandescent lights being far preferable in this respect to an arc light, Auer, Nernst or mercury light. His experiments further showed that the impurities in the air of cities absorb the ultraviolet rays so that they lose their bactericidal action on the air. The composition of city air renders it an impenetrable barrier for the ultraviolet rays unless high winds keep the air constantly replenished. It is not necessary, however, he adds, to send persons to a great distance to get pure air—a few miles beyond the city limits the ultraviolet rays display their full powers again. This should be borne in mind, he suggests, in selecting a site for a hospital.

59. Intestinal Dyspepsia.—Cade applies this term to habitual functional disturbances in the intestinal digestive process, independent of any lesion in the bowel. He discusses in turn the clinical manifestations, causes, effects elsewhere, diagnosis, prognosis and therapeutic indications. The most common form is that due to lack of sufficient gastric juice, and this indicates treatment with acids. With pancreatic insufficiency the acids should be supplemented with the ferments and lime salts. With a lack of sufficient bile, an extract of bile can be given, with sodium and magnesium salts. In all the forms special attention should be paid to the always predominant nervous element. A well conducted course at a spa is often particularly useful in permanently curing intestinal dyspepsia, selecting the waters best adapted for the patients with the diarrheic or constipated form.

62 Jonges' Position to Enlarge the Outlet of the Pelvis During Labor. (L'agrandissement du diamètre bis-ischiatique.) A. H. M. J. Van Rooy.

60. Loss of Lime During Pregnancy and Its Clinical Importance.—Marquis states that there is evidently a physiologic loss of lime during pregnancy, manifested by the looseness of the pelvic articulations; if it reaches a pathologic degree there is pain in the symphyses, and this he regards as the first stage of osteomalacia, believing that this degree of osteomalacia is quite common; in the second phase, there is considerable pain in the bones and walking is difficult, but the pelvis is not deformed. The third stage, in which the pelvis is actually deformed, is the only form of the affection recognized by other authors to date, and this is why the prognosis of osteomalacia is generally considered so grave. Examination of the proportion of lime in the blood is a reliable method of determining the condition in regard to lime waste. In two typical cases described in detail, the blood contained 0.12 per thousand lime in one and 0.162 in the other, instead of the normal average of 0.052 for the pregnant woman. The proportion of lime in the blood has always paralleled the severity of the osteomalacic disturbances in his clinical experience. The disturbance in osteomalacia is a decalcification while in rachitis it is more impossibility of recalcification. The decalcification in pregnancy is probably due to some disturbance in ovarian, suprarenal or similar functioning, with a predisposition afforded by frequently repeated pregnancies and deficiency of lime in the food.

- 63 *So-called Primary Neuralgia of the Rectum E. Parmentier and J. Foucaud.

63. **Neuralgia of the Rectum.**—In this article two typical cases are reported of primary rectal neuralgia. One was a butcher of 36 with intense paroxysmal pain in the region of the rectum, the other was a woman of 46. In her case the pain came on soon after eating and lasted for nearly three hours. In both cases there had been a preceding enterocolitis. Both patients were much benefited by a general brief tepid douche followed by local hot douches to the region. The application of heat in this way cured the first patient completely and the second is nearly cured and there has been no recurrence in either case for more than a year. The history, symptomatology and the diagnosis by exclusion are discussed and the benefit from local heat emphasized.

- 71 *The Relics of Tubal Abortion and Their Diagnosis. (Les reliquats de l'avortement tubaire.) F. Lejars.

71. **Retrospective Diagnosis of Tubal Abortion.**—Lejars regards a prolonged continuous blood stained uterine discharge as an important aid in differentiating tubal abortion; even if the proportion of blood is small its persistence for two up to five weeks is characteristic and absence of blood in the vaginal discharge is strong evidence against a recent hematocoele. The slight hemorrhage seems to persist longer after tubal abortion than after rupture. Incomplete expulsion of the ovum is also liable to keep up the hemorrhagic discharge, and he relates some instances of such retention of the placenta with the tube open and of total retention with the tube closed. The small encapsulated collection of blood may be taken for a fibroma and the resulting disturbances for inflammatory processes in the adnexa or in the uterus. Certain cases of tubal abortion have been diagnosed as a hemorrhagic metritis and the uterus was curetted when this organ was sound and the trouble was in the tube beyond the reach of the curette. It might possibly have been detected if the adnexa had been systematically palpated. The tubal abortion may not have been recognized as such and the discovery of the small encysted collection of blood in the pelvis years later may be a puzzling find.

75. **Technic for Injections into the Trigeminal Nerve.**—Offerhaus has been working out a method for certain and safe localization of the nerve for deep injections of alcohol, etc., in treatment of chronic trigeminal neuralgia. He reviews the history of the method and lauds its efficiency. The ancient Greeks knew that the dimensions of the human body are proportional to each other so that, given certain measurements, the others can be estimated from them, and he has found that this applies also to the skull bones and to their various parts. Comparative measurements of 60 European skulls in the Groningen museum of anatomy showed that the distance between the oval foramina is always equal to the distance between the alveolar processes measured beyond the last molars at the point where the palate process joins the lower jaw. The distance between these points is readily determined by measuring in the mouth. Eleven instructive illustrations and diagrams show the conditions and the various laws he has worked out from this material and his experience with deep injections in 8 cases. The laws of practical importance are that the distance between the inner side of the alveolar processes back of or beside the last molars, is equal to the distance between the round foramina. The distance between the outer side of the alveolar processes measured beyond the last molars is equal to the distance between the oval foramina; it is also equal to the distance between the outer sides of the maxillary tuberosities. The distance between the oval foramina and the outer side of the maxillary tuberosity is equal also to the distance between the round foramen and the outer side of the malar bone. In practice, therefore, it is necessary to know only the distance between the inner side of the alveolar processes and the distance between the maxillary tuberosities to know the point where the needle inserted will hit the third branch of the trigeminal nerve; if these measurements are respectively 5 cm. and 14 cm.

14—5

then the oval foramen lies at a depth of $\frac{14-5}{2} = 4.5$ cm.

2

The same principle applies also to the second branch and the round foramina. In order to determine with precision the exact direction to give the needle, he has devised graduated calipers with an adjustable rod in the end of each branch. The calipers are applied to the maxillary tuberosities and the rods are adjusted so that they project in a single straight line and the needle is introduced along this imaginary line running between the tuberosities. The needle first pierces the parotid gland, then passes in front of the maxillary articulation, through the rear wall of the masseter muscle and through the external pterygoid, and then reaches the third branch of the trigeminal nerve just before it divides. No large vessels are encountered on the way. To reach the second branch, the distance between the zygomas is determined in the same way as also the imaginary line connecting them; the calipers are applied to the middle of the malar bone about 1.5 cm. behind the point where the ascending and horizontal portions meet. The needle is introduced just above the zygomatic process, or, if it is desired to hit the second branch where it emerges from the round foramen, the needle is introduced just below it, the point of the needle directed a little upward and backward. The above technic locates the nerve within a few millimeters unless there is marked asymmetry of the skull, Offerhaus declares, and the simple method of deep injections is thus rendered accessible to all. He advises injecting a little alcohol into the peripheral foramen at first, and then, if this does not cure, making a deep injection. General anesthesia is unnecessary and actually detrimental. He adds that the entire domain of the second and third branches of the trigeminal nerve can be readily and effectually anesthetized by a single injection of a small amount of an anesthetic to reach the nerve as it passes out from the round or oval foramen.

88 Idem. (Behandlung der Tuberkulose mit I. K. in der Landpraxis.) W. Pumr.
89 Idem. (Erfolgreiche Anwendungswelse des "I. K." Spengler bei der Behandlung der Tuberkulose.) Westphal.

86. **Treatment of Tuberculosis.**—Benöhr states that Spengler regards the red corpuscles as the main source of production and storage of the immune bodies, and he obtains his I.K. (Immun-Körper), to serve as a tuberculin, from the dissolved corpuscles of artificially immunized sheep and rabbits. Benöhr tabulates the details of 130 cases of tuberculosis in which this treatment was applied at Davos, and Pumr of 46 other cases while Westphal relates his experiences with it at Hannover. The conclusions of the writers are all favorable as to its efficiency. Spengler has made a special study for nearly twenty years of the combination of tuberculosis and syphilis. An inherited syphilitic taint is found underlying the tuberculosis in more cases than is generally recognized. Syphilitic involvement of the lung is comparatively frequent although it is difficult to produce anatomic proof. The syphilitic lung is inclined to be "fleshy," hypertrophied, with a tendency to cirrhosis in time. A characteristic auscultation finding over these "fleshy" lungs is a murmur (Rauschen), more frequent over the middle and lower lobes than the upper, corresponding to the more usual location of syphilitic changes in the lung. This murmur is generally restricted to the terminal phase of inspiration and the beginning phase of expiration. With tuberculosis combined with syphilis the larynx is frequently involved and this is often the primary process. The bronchi also are notably involved, especially with acquired syphilis. Auscultation reveals this syphilitic bronchitis by the bronchial symptoms and a rattling or a snoring sound. Another sign is the lack of proportion between the apparently extensive pulmonary process and the well nourished, healthy aspect of the patient. The syphilitic-tuberculous sputum is large in amount, mucous or mucopurulent, and the microscope shows numerous cellular elements with fragmented nuclei in contrast to the sharp outlines of the cell nuclei under other conditions. Tubercle bacilli are few and far between, even with extensive processes in the lung. Sometimes spirochetes can be discovered in the sputum. Vigorous mercurial treatment is contraindicated in the tuberculous, and only mild measures can be used. Many obstinate cases of pulmonary tuberculosis yield to tentative antisiphilitic measures; the outlook is more promising in the young and in the stage of inflammatory hypertrophy. In one such case a man had had pulmonary symptoms for 26 years; the cough had increased during the last six months and there was fever and a few tubercle bacilli were found. He has healthy children and no history of syphilis, but 20 drops of tincture of iodine twice a day in milk banished nearly all the râles in less than two weeks and by the end of two months the temperature was normal, the expectoration and râles had ceased and the patient had gained many pounds in weight.

97 *Treatment of Chronic Lead Poisoning with Fixation Abscesses. (Zur Behandlung des chronischen Saturnismus mit Fixationsabscessen.) V. Hinze.
98 Warning for Caution in Application of Wassermann Syphilis Reaction in Diagnosis. A. Freudenberg.

90. **Sudden Blindness in the Elderly.**—Uthoff reports two cases of sudden bilateral blindness which he ascribes to a peripheral, basal affection of the optic nerve, basing his diagnosis on the exclusion of all other probable causes. In the first case nothing pathologic could be found in the woman of 71 except a tendency to arteriosclerosis. The only plausible explanation seems to be bleeding from an artery at the base of the brain, the blood entering the sheath of the optic nerve, or compressing it after encapsulation of the minute hemor-

rhage. The cerebrospinal fluid was limpid on lumbar puncture five weeks later. In the second case there were signs of a preceding tendency to neuritic atrophy of the optic nerve although the patient, a man of 59, had not been conscious of any disturbance; a basal hemorrhage had probably occurred also in this case.

91. **Tuberculin Treatment of Kidney Tuberculosis.**—Wildbolz states that microscopic examination of the kidneys in 5 cases after prolonged courses of tuberculin treatment failed to reveal any tendency to healing of the tuberculous processes in the kidney under the influence of the tuberculin. In 4 of the patients the tuberculosis was restricted to one kidney and the conditions were unusually favorable for a cure if the tuberculin treatment had been able to effect such, but in every instance the disease progressed and nephrectomy became necessary in time. The general health persisted good and the tuberculous process had not progressed to the cheesy phase or cavity formation notwithstanding its long duration, up to 8 years in one case. There were no evidences in any of the kidneys of an injurious action from the tuberculin. He also reports 3 cases in which the tuberculous process in the kidney apparently healed under conservative measures without tuberculin, and the patients were in good health for 3, 2 and 9 years before the symptoms flared up again and the long advised nephrectomy was permitted. Such spontaneous remissions and apparent clinical cures impose extra caution in estimating the effect of tuberculin. His conclusions from these and other data cited are that tuberculin has a general favorable, toxin-binding influence in case of kidney tuberculosis but no appreciable local action on the lesions. In his 31 cases the general health almost invariably improved under the tuberculin but no patient was cured or even relieved from his local disturbances. Extreme caution is necessary if tuberculin is given in advanced kidney tuberculosis on account of the extensive absorption of the toxins of the tubercle bacilli in the kidney process, flooding the system with tuberculin from within. In early cases of unilateral kidney tuberculosis, a trial of tuberculin is justified, especially in the young. By this means it may be possible to benefit in some cases, and the constant oversight required with tuberculin treatment enables a prompt decision as to when nephrectomy should be advised or enforced, while the findings in the kidney will throw light on the actual action of tuberculin in such cases. We must ask more of the tuberculin with kidney than with pulmonary lesions, as in nephrectomy we have a means of actual definite cure, while there is no such resource with pulmonary lesions.

97. **Fixation Abscess in Treatment of Lead Poisoning.**—Hinze reports a case in which unmistakable benefit was derived from a fixation abscess made in the thigh by subcutaneous injection of 1 c.c. of turpentine. Although the patient in this case had had nothing to do with lead for ten months, yet 0.089 per cent. of metallic lead was recovered in 1.528 gm. of pus from the abscess. The patient in this case, a type-founder of 41, suffered also from tuberculosis, alcoholism and arteriosclerosis and there were signs of interstitial nephritis, but he bore the fixation abscess without apparent harm. At autopsy a few months later only traces of lead could be found in the liver and none in the bone marrow. J. Carles reported last year 2 clinical cases and considerable experimental research, all confirming the action of the harmless fixation abscesses in aiding in the elimination of lead in cases of industrial lead poisoning. He calls it "leukocyte venesection."

 109 *Treatment of Deformities of the Feet. (Weitere Beiträge zur Behandlung von Fussdeformitäten.) J. Fränkel.

101. Secondary Infection with Tubercle Bacilli and Their Saprophytic Growth.—Hart is a prosector and he protests against the assumption that children are infected with tuberculosis as generally as seems to be the case from the numerous positive responses to the Pirquet tuberculin skin test. Again and again in his experience the autopsies of children giving a positive Pirquet reaction during life have failed to reveal the slightest tuberculous lesion under the microscope. He thinks it is far more likely that tubercle bacilli may be located somewhere in the body, leading a saprophytic existence and causing no tissue reactions, but at the same time absorption of their toxins from their saprophytic growth may lead to the production of antibodies which in turn would give a positive reaction to the ultrasensitive Pirquet test although in reality there are no tuberculous lesions. To sustain these views he reports a demonstrative case in which a colony of tubercle bacilli were found living a saprophytic existence without trace of microscopic changes in the tissues in which the colony of bacilli were encooned. The cadaver was that of a locksmith of 51, with no tuberculous antecedents in the family. He had been coughing for several years and lately had become much emaciated. The physical findings in the right middle lobe suggested tuberculosis; there had been hemoptysis on one occasion, and after repeated negative findings a few tubercle bacilli had at last been detected in the sputum. The ocular tuberculin test with 2 per cent. solution of tuberculin was negative, weakly positive with a 4 per cent. solution, and the skin test gave weak positive findings. The clinical diagnosis was thus pulmonary tuberculosis and right empyema; autopsy disclosed, however, a primary cancer in the bronchi and no tuberculous focus in the lung or elsewhere, but a small colony of tubercle bacilli were found in the thick pus in the enlarged bronchus while the pus in the lung contained merely streptococci. He interprets the case as one of secondary colonization of inhaled tubercle bacilli in the stagnating secretion of the compressed bronchi, where they led a saprophytic existence, but generated toxins which were absorbed in sufficient amounts to account for the reactions to the tuberculin tests.

105. Treatment of Flat-Foot.—Momburg remarks that it is absurd to attempt to correct a twisted and sunken arch only by sustaining the center of the arch; by pushing the bases of the arch into their proper place the central arch will resume its proper position. This is the basis for his flat-foot insole. He leaves the arch alone but strives to bring the heel into pronounced supination while the bones in the ball of the foot are brought into a plane perpendicular to the axis of the leg. The heel and the heads of the metatarsal bones are the supports for the arch of the foot, and by bringing them into their proper place the arch reassumes its normal shape. He accomplishes this with a rubber, wedge-shaped insole, the slant inward and forward, the piece fitting under the heel and stopping just short of the ball of the foot. A spring below and a leather sole above hold the parts in place; the supports of the foot are forced into the proper position and the arch takes care of itself. He states that this insole has freed many patients from long rebellious flat-foot disturbances. This simple and cheap insole can be worn with any shoe with a broad low heel.

108. Beethoven's Deafness.—The first signs of Beethoven's deafness were noticed about the age of 25 and he tried one method of treatment after another, the deafness growing constantly worse and the subjective sounds—the *Sausen und Brausen*—tormenting him, as he says, like a demon day and night. He turned from one physician to another and finally to quacks, and various ear trumpets were devised to help him but without benefit, some by Mälzel, inventor of the metronome. He succumbed finally, at the age of 57, to cir-

rhosis of the liver. The Eustachian tubes were found at autopsy much thickened, with cicatricial depressions near the mouths, the auditory nerves shriveled and without medulla, and general signs of otosclerosis. The convolutions of the brain were twice as deep and numerous as in the average brain, the skull very thick. The loss first of the high tones shows that the deafness was primarily of nervous origin while the subjective sounds revealed the otosclerosis which the autopsy findings confirmed. Beethoven had smallpox in youth and a typhoid affection a few years before his deafness; the typhoid, Jacobsohn remarks, may have been responsible both for the otosclerosis and the bowel trouble from which he suffered. There was nothing to suggest syphilis, inherited or acquired, except possibly a circumscribed thickening of the right parietal bone of the skull which, according to the pictures, resembles those observed on a basis of syphilis. The autopsy report was signed by J. Wagner, Vienna, 1827.

109. Treatment of Deformities of the Feet.—Before correcting the deformities, Fränkel loosens up the foot by a preliminary superheated air bath in the glass boot. He gives illustrations of various devices for correction of flat-foot and club-foot and the technic for treatment of club-foot after it has been once corrected.

 117 Familial Occurrence of Tetany. Coler.
 118 Staining Process for Fibrin. (Zur Theorie der Fibrinfärbung.) K. Lennhoff.

110. Pseudo-putrid Processes in the Air Passages.—Eichhorst reports a case in which a putrid empyema existed in the pleura but without perforation of pus into the air passages. The putrid odor of the breath and sputum and the changes found in the air passages at autopsy were evidently due solely to penetration of the putrid gases into the lungs and their action on the tissues. In two other similar cases the women succumbed to the progress of a putrid empyema in the pleura although the breath and sputum had never had a putrid odor, and no pathologic findings were encountered in the air passages or elsewhere.

112. Importance of Focal Reaction to the Subcutaneous Tuberculin Test.—Otten regards the reaction at the focus after administration of tuberculin as the most reliable means at our disposal for estimating the actual condition of the focus, whether it is active or in a latent or healed phase. Neither the local or general reaction with the subcutaneous test is decisive in this respect while the focal response gives illuminating findings. In 324 cases in which the subcutaneous tuberculin test was applied, 60.8 per cent. of the patients responded with both a focal and a general reaction; 7.4 per cent. with a focal reaction only; 23.5 per cent. with a general reaction only, and 8.3 per cent. with no reaction of either kind. The patients were those merely suspected of a tuberculous apical process in the lung in an incipient phase. In the 221 cases giving a focal reaction this consisted of development of dulness in 6 cases, exaggeration of previously existing dulness in 78; development of dulness and new râles in 3 while in 66 the existing dulness became more pronounced and râles were heard for the first time or became more pronounced in 10 cases. In 40 cases râles were heard for the first time while the dulness persisted unmodified, and in 9 the râles increased, the resonance persisting normal. Besides these findings the patients frequently complained of a vague or sharp pain in the region of the lung involved. In some cases a cough developed for the first time or the expectoration

increased or commenced for the first time. In 3 cases there were traces of blood in the sputum, observed for the first time. In only 3 of the total 324 cases were tubercle bacilli discovered for the first time in the sputum after the tuberculin test. The symptoms of the focal reaction lasted as a rule only 2 or 3 days, occasionally for 4 or 5. The patients were kept in the institution for a few days after subsidence of the reaction and no harm resulting from the test was ever discovered. Later examinations have also confirmed the precision of the focal findings as three-fifths of the patients showing traces of a focal reaction have grown worse in the interim, notwithstanding sanatorium treatment, while the condition has persisted unchanged in almost every one of the cases not displaying any evidence of a focal reaction, although none has had sanatorium treatment. The reaction at the point of injection of the tuberculin, the *Stichreaktion*, did not parallel the other findings in most cases and does not seem to have decisive diagnostic value.

menced in No. 25.

119. Chlorosis and Its Treatment.—Morawitz protests against the assumption that chlorosis is essentially an anemia; in 28 girls with the classic clinical picture of chlorosis whom he has examined in the last six months, the proportion of hemoglobin was above 80 per cent. in nearly all, not below 60 in any, and frequently over 90 per cent. Notwithstanding this normal or nearly normal composition of the blood, the patients presented the typical symptoms of chlorosis and nearly all were cured by iron. He concludes from these and other experiences of the kind that the anemia is not the essential feature of chlorosis but only one among other symptoms. It is much more probable, he thinks, that defective or excessive functioning of the ovaries or some inter-related ductless gland is at the root of all the syndrome; the ovary alone cannot be responsible as ovarian organotherapy has not given encouraging results. Giudiceandrea has recently reported enlargement of the thyroid gland in fully 50 per cent. of his chlorotic patients examined. The fact that chlorosis develops exclusively during puberty is also suggestive in this line, as also that chlorosis may recur again and again in those who had it at puberty. Seiler found the hemoglobin percentage only 10 or 15 below normal in 51 cases of chlorosis, and all the symptoms disappeared under iron in 30 of the patients. He calls this condition "masked chlorosis;" among the 21 who were not cured by the iron were 12 girls with incipient apical tuberculosis. The iron evidently acts on the primary cause of the trouble; it is absurd to suppose, Morawitz declares, that the mere loss and recovery of such a minute hemoglobin percentage as the difference between 80 and 90 per cent., could elicit and banish the train of symptoms we call chlorosis.

123-124. Resection of Posterior Spinal Roots in Treatment of Spastic Paralysis and Painful Crises in Tabes.—Codivilla

reports a severe case of spinal spastic paralysis in a well nourished girl of 15 in which a little benefit was derived from resection of the second sacral and fifth and third lumbar roots on the left and of the second sacral and fifth lumbar on the right. He is convinced that the improvement in this case might have been attained equally well with the ordinary orthopedic operations, tenotomy, etc. The results might have been better, he remarks, if more of the roots had been resected. There seems to be a tendency to atrophy of the muscles on the side on which most roots were resected. Flürcken reports complete success from resection of the seventh to tenth dorsal roots inclusive in a case of painful crises involving the spine and thorax, the syndrome like that of exceptionally severe trigeminal neuralgia. The whole syndrome was cured by cutting off the region from communication with the central nervous system by resection of the spinal roots involved. Flürcken ascribes to Abbe of New York and Bennet, in 1888, the first suggestions of resection of the spinal roots as a means of curing violent neuralgia. Chipault in 1895 endorsed their suggestion, and Munro reported in THE JOURNAL in 1904 two cases of laminectomy and division of the posterior roots, but Foerster and Küttner first applied the method on a systematically outlined plan.

130. Simple Staining Technic for Living Spirochetes.—Meirowsky mixes methyl violet with a few drops of physiologic salt solution and rubs the colored mixture vigorously into the ulcerated primary sore or condyloma. As serum oozes it is found to contain the spirochetes stained a bright violet. The depth of the stain depends on the concentration of the coloring mixture; it works best when it is of such strength that the lipid envelop of the red corpuscles is a deep bluish violet tint. The refringens assumes a bluish violet tint, easily distinguished from the bright violet stain of the pallida.

131. Gangrene after Iodin Sterilization of the Skin.—Hindenberg reports two cases of an ax injury of the toes while splitting wood, in both of which he applied tincture of iodine according to the customary technic. When the dressings were changed two days later there were signs of commencing gangrene which he ascribes to penetration of the iodine into some gaping vessel entailing destruction of the vessel walls and consequent gangrene. The cases warn, he adds, against applying the tincture of iodine method to cutting wounds unless the cut surfaces are protected with gauze against the penetration of the tincture of iodine.

132. Action of Roentgen Rays on Tumors.—This communication relates the experiences with Roentgen-ray treatment of tumors at the Heidelberg Institute for Cancer Research in charge of Czerny. A favorable influence from the rays was undeniable but it is doubtful if they will ever prove reliable alone. The method fails sometimes in the apparently most propitious cases while again in others, apparently the least encouraging, surprising benefit may be realized. Operable tumors, it is reiterated, should always be removed but in the after-treatment the Roentgen rays may be usefully applied even in combination with fulguration or thermopenetration or other measures. When applied to an open wound, the Roentgen rays seem to act more effectually than when they have to pass through the skin. When an operation is impossible from any reason then the Roentgen rays should be applied as vigorously as possible, but not if there is a chance for operative measures later as in that case the over-exposures might have an injurious influence on the healing of the wound. This applies also to cancers on the limit of operability; preliminary Roentgen exposures may render them more movable and much facilitate their removal, but in such cases Czerny is always careful not to expose the region enough to induce much eczema. In the absolutely inoperable cases Roentgen treatment should be given a trial in every case, it is stated, as surprises in a favorable direction are always possible. But if only an aggravation follows the first set of exposures (5 or 6 H units over every point of the surface), it is useless to continue the exposures as when this was observed further exposures had no favorable influence in such cases. Especially unfavorable experiences in this direction were encountered with carcinomas of the mouth, tongue

and parotid region. Apparent success at first is not always a precursor of a definite cure; the melanomas were most disappointing in this respect, and certain cases of lymphosarcomas. After surprising retrogression of the tumors at first, they then entered a phase in which they ceased to be influenced by further exposures. The aim in Roentgen treatment is not to induce necrosis of the cancer but merely an elective injurious influence on the pathologic cells, destroying their vitality and leaving them in a form permitting their absorption, while at the same time the rays have a stimulating action on the neighboring tissues, starting proliferation in them. Unless the adjacent tissues are able to absorb the destroyed tumor cells, their destruction does no good. One great difficulty with Roentgen treatment of cancer, it was found, is that the different elements of the lesion possess a varying susceptibility to the rays; this difference may be striking even from cell to cell. Homogeneous radiosensitivity of the cancer, surpassing that of adjoining tissues, is the *sine qua non* of success.

142. Births after Suprasymphyseal Delivery.—Hartmann has previously reported 8 childbirths in women delivered by suprasymphyseal section and here reports 4 more cases. No mishaps were encountered in any case for which the previous operation was in any way responsible.

143. Perineotomy.—Markowsky states that v. Ott has made a practice of prophylactic section of the perineum since 1895 and now has a record of over 364 cases and is preparing a detailed and laudatory report on the method for the approaching gynecologic congress in St. Petersburg next September. He claims that the perineum is protected best by systematic incision.

145. Cancer in the Stump of the Cervix.—Hinterstoisser has had carcinoma develop in the stump of the cervix in two cases after the Chrobak supravaginal amputation of the cervix for myoma. This makes ten cases on record of this contingency but he declares that this percentage is too small to detract from the value of the Chrobak technic, although it imposes the necessity for regular and frequent examination of the woman afterward.

150. The Albumin Reaction in the Sputum.—Trona applied Roger's technic in 44 tuberculous cases and 35 of various other affections and obtained positive findings only in the tuberculous cases and in 9 with heart disease and albuminuria. The sputum is mixed with salt solution and a few drops of acetic acid are added to precipitate the mucin. The whole is then stirred and filtered. The filtrate is then boiled or treated with trichloroacetic acid to reveal the presence of albumin. The albumin indicates that the sputum is not a mere superficial secretion but comes from some deep-seated inflammatory process.

151. Hemostasis by Inflating Tubing.—Pomponi uses a rubber tube 2 or 3 cm. (1¼ inches) in diameter, the ends held with forceps. Air is slowly pumped into the tube and by this means compression is exerted sufficient to arrest pulsation below without injury of the tissues, even when the compression is kept up for hours. He uses this contrivance for the Momburg belt constriction and states that the disturbances were slight and transient even after six or seven hours' application in his experiments.

SOME ASPECTS OF THE MEDICAL CURRICULUM OF TO-DAY AND OF TO-MORROW

A. W. MEYER, M.D.

Professor of Human Anatomy, Leland Stanford, Jr., University
STANFORD UNIVERSITY, CAL.

That he who makes a prophecy risks his reputation, is an old adage. I accept its truth. However, only he who hath can lose. Moreover, it is not my purpose to suggest or to forecast an ideal curriculum, but simply to discuss certain aspects of present-day curricula in our stronger medical schools, and to call attention to changes which may be anticipated, or perhaps found advisable, even now. Others may be necessitated in the future—likely in the near future—while some have already been incorporated by a few of the leading medical schools of the country. It is indeed to be regretted that there is such a distance between the vanguard and the rear-guard of our medical schools, and that the curricula of many of them have undergone so few transitions outside of those necessitated by the very recent changes in requirements for admission. To be sure, change does not necessarily imply progress, but its absence surely suggests stagnation. This, I take it, applies to a certain extent to both the nature of the courses and the time devoted to them.

RIGID CURRICULA

With a few notable exceptions, one of the most prominent characteristics—yes, *the* most prominent characteristic—of the curricula of our medical schools is their rigidity. As a rule, the entire course is clearly marked out in every detail, not for one or for two years, but for four. In actual hours, this time varies from about three to seven thousand! Regardless of his previous training—or lack of it—the student is put into this educational strait-jacket from the first day of his four-years' course to the last, the strongest locking step with the weakest. His tasks are meted out to him from 8 to 9 in the morning until 5 to 6 in the afternoon, for five or even for six days in the week.

That this is not an overstatement of the facts can easily be learned by a review of the schedules themselves, and of statistics available to everyone. Few hours indeed are left to the disposal of the student, in which to find himself, to develop his own inclination, and to exercise his own initiative, to say nothing of recreation. Under these conditions the able student must abandon—or at least defer, which is frequently equivalent—any scholarly ambitions which he may cherish, unless good fortune and good health enable him to avail himself of vacation days. In this connection it is frequently urged that the curriculum must meet the needs of the general practitioner. This is true, but it is not the whole truth, nor does it follow that the best general practitioners are

produced by a trip-hammer process of education. The medical curriculum, it seems to me, can and should provide adequate training for the future general practitioner without depriving him of all opportunity to cultivate a proper scientific attitude toward his future work. I am well aware that not every country practitioner will make a Robert Koch, and that the exhausting humdrum of so-called practical routine drill, which sometimes unfortunately fills all the hours of the day and night, would never make a capable physician, much less a Koch. Yet it would be foolish to deny that the atmosphere, in which the medical student lives and the opportunity given him for the cultivation of a proper attitude toward his work often determines his later career. The cultivation of this habit cannot be deferred until practice is begun. He who comes not naturally by it, or belongs not to the few who acquire it in their pre-medical work, must of necessity, then, be given the opportunity to acquire it during his medical training. For few indeed are the noble minds and resolute souls that can keep latent, with any hope of fruitful revival, scholarly ambitions dormant for a decade.

THE NEED OF DEVELOPING THE SCIENTIFIC SPIRIT

But the general practitioner has every need of being a progressive physician. He, above all, needs that attitude which can appreciate the value of a fact regardless of any obvious relationship to pressing life-problems or its immediate utilization, to preserve him from hopeless deterioration and inefficiency. It was said long ago, and often since, that "a little learning is a dangerous thing." A broad grasp of some subject—it matters little what—is essential for the acquirement of abiding interests. But how under the stress of the present-day curriculum with its increasing multiplicity of subjects can the student "drink deep"? Hence "taste not the Pierian spring" becomes his unconscious and willing or unwilling motto.

I take it that medical students can be unmade as well as made, and that to discover and to preserve the capable is as important as to eliminate the incapable. A heroic soul may survive. Poe did; Macaulay did; Darwin did; John Hunter would have, but demurred. Unfortunately not every medical student comes to us with the curiosity of childhood preserved, yet most men after all have something of what Lichtenberg called "das rastlose Ursachenthier" in them. To preserve and to cultivate these natural endowments is a high duty and sacred privilege, it seems to me. A fuller recognition of it would, I believe, result in inestimable benefit to mankind, and redound greatly to the glory of the medical profession. Perhaps this has received tacit recognition. Open recognition is needed, however. It is no excuse to say that recent progress has been so great and the subjects so many that this is impossible. We have sev-

eral notable examples in this country which have repeatedly and long since demonstrated that it is possible to have the medical curriculum follow closely in the wake of scientific progress and yet leave room for the play of individuality. Besides, will not subjects increase and progress continue? Assuredly, the present golden days in medicine will not be followed by dark ages again! And if so, this would be all the more reason for preventing *den rastlosen Ursachenmensch* from becoming *ein gleichgültiger Maschinenmensch*.

ELECTIVE COURSES

Several of our leading medical schools have already reduced the required work, both prescribed and elective, to a minimum, and made all other work elective. Since the elective system in colleges and universities has been so fully and so ably discussed in recent years, a full discussion will here be avoided. Its dangers, I believe, can be safeguarded by the group system, and in other ways. By its introduction, well-trained and ambitious students will be given an opportunity to get more than an elementary knowledge of some subject. More thorough work is likely to result, because the student takes a more intelligent interest in his work, and is encouraged to think for himself. Departments of instruction must of necessity be better equipped in men and means to afford able students an opportunity. Hence departments barely able to afford minimum requirements will cease to exist, never having had any good *raison d'être*. For, as any tyro knows, a machine that always runs at its maximum is not an efficient or an economical one. Even the general practitioner will have better opportunities through the enrichment of the course by a number of elective and optional subjects. Courses that are not thorough will not be chosen save by the weaklings, and this again will bring its own reward to both students and professors. Individual departments will be more self-respecting, for the younger men on the staff, being assured an impartial hearing, now have every incentive to show their mettle. Being placed in direct and equal competition with all, they will often act as a powerful leaven in the whole department. These men will thus be given an opportunity to develop themselves, and to lay the foundation of a later career under the guidance of those whose disciples they are. And even if none of them prove a Huxley, yet the day is sure to come when, as Virchow said: "We are filled not alone with admiration for the hero, but at the same time with grateful recognition of the institution which planted the seed of high achievement in the soul of the youthful student."

Further criticisms—all of the friendliest kind, to be sure—are made with the greatest reserve, since they mostly concern matters outside of my own work. If, however, this imposes silence, then manifestly there can be no mutual consideration and cooperation, and hence no progress in this matter. If therefore I shall look boldly over the fence which bounds my own lane into my neighbor's field, I trust I shall not be regarded a trespasser.

PURE AND APPLIED SCIENCE

Pasteur, it will be recalled, said applied science was related to pure science as a tree to its fruit. One of the trees growing here and there which we must fertilize, water and prune, lest the command go forth, "Cut it down; why cumbereth it the ground?" is applied anatomy. There seems to be a good deal of confusion as to what applied anatomy is. In the past, tree and fruit have been confused, or even considered apart from each

other. What the great master meant, I take it, was to foster well the tree, and the fruit would appear in due season. Perhaps it is this fine conception of science which has been responsible for the absence of special courses in applied anatomy in some of our best medical schools. The want in the past, it is clear, has been in the absence of those who fostered the tree, and in the multitude of those who, fixing their eyes solely on its golden fruit, let the neglected tree wither in sterile ground before them.

ANATOMY AND SURGERY

In some schools, applied anatomy seems to be the equivalent of or limited to surgical anatomy. In others, it is transformed into topographical anatomy, or even into operative surgery or is restricted to regional anatomy. The mere fact that so much confusion exists in regard to an old subject throws a strong and very interesting side-light on the whole matter. It also suggests that in many cases probably nothing very definite, or very indispensable even to the training of the general practitioner, was included. For if it be topographic anatomy it should be called so. If, on the contrary, it be surgical anatomy that is taught, then apparently only a portion of the field of applied anatomy is covered. Since, moreover, the recent graduate is not to do any major operation, there would seem to be no adequate reason why much that is at present given under surgical anatomy should be included at all in the required work of the curriculum.

It is interesting indeed that, at a time when surgeons are unanimous in declaring that it is wholly unjustifiable for any graduate in medicine to do major surgical work without prolonged and thorough hospital training, courses in operative surgery should still be insisted on! It is true that I am not fully informed as to the details of the subject-matter covered in many of the schools. But it is known what texts are used, and that all manner of major operations on the cadaver from the vertex to the soles are frequently done before, by, and with students who have not even finished their dissections. In other cases, work on animals is introduced, and students take turns in gaining facility in the use of hemostats, by catching severed vessels quickly. As to the care of the material, and the conditions under which this work is often done, I forbear to speak. Indeed, were the schools in which these things happen less prominent I would gladly forget it. Besides, I am not concerned with the character of the work, but with the work itself. Why should any student, it may be asked, spend the precious time of an overcrowded curriculum studying the details of difficult operations in surgery? Such operations, for example, as the removal of the Gasserian ganglion (lately called Gasserectomy—poor Gasser!) prostatectomy, lateral lithotomy, pyloroplasty, intestinal anastomoses, etc., etc. These all, and many others, are often included in surgical anatomy and operative surgery.

But no matter how ideal the conditions under which this work is done, or how ably it is taught, it certainly is not consistent or excusable to teach students these things, and then to condemn them for doing them. What wonder that after such teaching recent graduates attempt to perform all manner of major operations to their own sorrow, to the discredit of their teachers and to the harm of the public. It is difficult indeed to see why able teaching in human anatomy and in surgery would not make these special courses largely unnecessary. The trend of medical education is still in the

main a practical and not a scientific one. In this connection, it may pertinently be recalled that Helmholtz and many since attribute the dominant position of Germany in medicine to the fact that the Germans had purely ideal aims for the cultivation of science without any immediate prospect of practical utility. We Americans, on the contrary, have often been credited, and rightly so, with being unusually quick to see the practical relations of facts—provided we knew of the facts—but have we been equally active or fortunate in the revelation of those facts? From these things, and from the examples of certain excellent schools, one is compelled to conclude that it would be in the interests of all to eliminate a large part or the whole of these courses, or at least to confine them to the few who become surgeons, and thus withhold such knowledge from many a young physician who might be tempted to take a chance.

TOXICOLOGY

If I have correctly understood those fully competent to speak, most graduates from college and university courses have not had sufficient training in chemistry to enable them to take up the subject of toxicology to advantage. This, to be sure, is no reflection on these institutions. If toxicology belongs to higher analytical chemistry, it must be true that a thorough training in analytical chemistry itself is a *sine qua non* for entrance on toxicologic work. I am well aware, of course, that toxicology as given in most medical schools is nothing so self-respecting or so advanced as this. Is it really toxicology, then, and should it be given apart from the other chemical work in the medical course? I do not presume to answer this, though I am well aware how able teachers in both chemistry and pharmacology regard the matter. Their opinions are available. It must be evident to everyone, though, that if toxicology, so-called, were eliminated from the medical curriculum, some future practitioners might be deterred from supposing themselves capable of acting as expert analysts in medicolegal cases. Almost every week sees some overzealous and benighted doctor of medicine making a spectacle of himself and of his profession before a court of law and before the public. While the elimination of toxicology from the list of required work would not change human nature, it might and probably would change the attitude of many a general practitioner to this matter and eliminate it from licensure tests.

SLIGHTED SUBJECTS

If the introduction of the elective principle into the curriculum be thought unwise, because of the lack of maturity and preparation on the part of students, or for other reasons, it surely would not be difficult to find substitutes for any of the above-suggested eliminations. Among the subjects of direct and material importance to the general practitioner are at least two which, according to authorities in them, have so far not received adequate attention. These are pediatrics and psychiatry. Material for instruction in these subjects is available everywhere. What is needed is the correlation of the facilities of existing institutions and the erection of special hospitals or hospital wards for childrens' diseases and particularly for mental cases.

The equipment of childrens' wards and of wards for contagious cases in childrens' hospitals would afford every medical student an opportunity to obtain firsthand knowledge of the diseases of early infancy and of the care of young children. The training so gained, in addition to that obtained in the maternity ward, and

dispensary, would equip the young physician in a way which is now largely impossible. To-day, most graduates go into practice without adequate knowledge of contagious diseases in general. For the lack of hospitals for contagious diseases the attitude of the public is no doubt partly responsible, but what can be more unfortunate or embarrassing in the career of the beginner than to see measles, chicken-pox, scarlet fever, diphtheria, etc., for the first time in his life as a student or practitioner of medicine? Unless he is tactful, mother or nurse may correct his diagnosis and seriously handicap him at the very start.

Modern civilization no longer tolerates the *tortura insomnia*, and many other relics of past barbarity, in the treatment—or what the future will call mistreatment—of mental cases, but contents itself chiefly with benevolent incarceration. Surely much less could not be done in this day. To immure the helpless patient and leave him to his own devices, or those of unskilled and untrained attendants makes not for progress. With the doors of the general hospitals barred against him, nothing but the private sanitarium remains for the patient with incipient mental disease. Under present conditions, there is written over the doors of many of these, as well as over the doors of many of our asylums, "He who enters here leaves hope behind." This would be less pathetic were it less true. And until the general hospital will admit such patients as readily as it does patients with the acute infectious diseases, the medical student at best will likely be compelled to begin his career with but a text-book knowledge of them. As a result, he is almost sure to overlook impending danger and fail to recognize the actual conditions until the catastrophe breaks on his patient.

These things have been said with some reluctance, and with full appreciation of the services of the many devoted and unselfish men, whose all too busy lives are spent in the noblest of causes. Any one who knows what is done at the present day, however, and realizes what could be done, and is done elsewhere, for the mentally afflicted, cannot help but feel the injustice and in many respects the hopelessness of the present situation.

NEW SUBJECTS

I am also persuaded that the near future will see the relegation of pharmacognosy to the pharmaceutical schedule, more emphasis placed on physiology, on psychology, and some aspects of therapeutics, and the correlation of therapeutics and pharmacology and that instruction in pathologic physiology, preventive medicine and the allied subjects of sanitary science, public health, hygiene, and vital statistics will be given. To enlarge on the necessity for these in the curriculum for the general practitioner, seems unnecessary. Moreover, it is not my purpose to do more than to call attention to their frequent absence.

The devotion of more time to some of these subjects, and the introduction of others, will greatly enrich and strengthen the medical curriculum. It will widen the horizon and broaden the grasp of the general practitioner, as well as of the future investigator. I know full well that to introduce these things will require very material additions to both staff and equipment in many cases—for no instruction is better than faulty instruction. And here may it not be said with entire courtesy that retrenchment in some of the recent expansions would seem advisable on the part of those colleges and universities which have assumed responsibility for the

conduct of a medical school, rather than to jeopardize the efficiency and to limit the usefulness of the future practitioner of medicine by a false economy? Surely this matter is too serious a one for the student, for the public and for the institutions concerned to be regarded lightly.

IMPROVEMENT ALREADY SECURED

Besides, our beacon-lights of medical education seem as yet unable to reach the eyes of all. To be sure, the progress made in the last decade is cause for much congratulation. The medical sciences have found a firm foundation, and further differentiation has already begun in clinical medicine. Moreover, the higher standards in medical education adopted through the combined efforts of the Council on Education of the American Medical Association, the Association of American Medical Colleges, state boards, and the Carnegie Foundation for the Advancement of Teaching, bid fair to have the most far-reaching and permanent effects. For, although schools with the highest standards have long exerted the best of influences, their splendid example unfortunately needed the reinforcement of publicity. They were often said to train theorists, unpractical men, good enough for teaching, while the pride of the rest was the training of the general practitioner. For him, low standards of admission and crude equipment were supposed to be sufficient. The fancied need of the general practitioner, or even the needs of various parts of the country for general practitioners of medicine, have often served as an excuse for wholly unjustifiable conditions. Against these assumptions, and against the separation of medical schools from universities, Brücke raised his voice long ago, and his words, though often unheeded, are still true.

THINGS DESIRED

Publicity of the facts has done much, and will do more. The forthcoming report of the Carnegie Foundation will no doubt mark an epoch in medical education. It is heroic treatment this, but the results will stand as an enduring monument to the credit of the medical profession with whom the movement for reform started. That this movement shall not cease till double standards in state boards, unjustifiable conditions within our schools, and many other things, are corrected, is the desire of every one who has the best interests of medical education at heart. From such, and from no other motives, the above criticisms and suggestions were made by one who is willing to sit at the feet of those who have grown great and gray in the service of medicine in this, or in any other day.

THE IMPORTANCE OF BEDSIDE TEACHING

FRANK W. HORN BROOK, M.D.
BOSTON

In this day when laboratory methods are so strongly emphasized and practiced and when there is such a surplus of theoretical teaching, let me call the attention of the medical profession, and especially the teaching branch of the profession, to bedside teaching. Teaching medical students at the bedside, while they are still in school, how to recognize a patient who is really seriously sick from one who is only mildly ill; how to recognize what the patient is suffering from; how to prognosticate as to recovery and what are the practical, the sane methods of treatment in each individual case as learned from the

actual case by individual examination—this form of teaching, which is of the utmost value, is not carried out in any of the first-class medical schools with which I am familiar.

I would urge the great value and the absolute importance to medical students of continuous and painstaking observations on the sick at the bedside, the careful examination, complete in detail, and the thoughtful, serious effort at forming conclusions when at the side of patients who are confined to their beds because of the gravity of their afflictions.

When a medical student is given his degree, it certifies that he is prepared to practice medicine and surgery, but he is not; he must spend two years or more in a large hospital or become the assistant of some busy practitioner before he is even fairly well fitted to practice his profession, because his medical work at the school has been too theoretical; because he has not seen and handled any really sick people to speak of; he has not had anything like enough of individual bedside teaching.

Work in the out-patient departments, examining one or two patients in the hospitals and writing theses on them, followed with discussions before the class, case teaching from printed slips, occasionally being called down from the amphitheater to feel a pulse, to palpate a tumor, to listen to a heart, to examine reflexes—these are valuable, but such opportunities to handle the living patients are handed out in homeopathic doses, and it is for more bedside opportunities for the medical student that I am pleading. It is of small value to look at a patient from an amphitheater and listen to a discourse, as compared to the value of having all the students divided into small groups, by means of small sections, personally studying and handling the patients.

It is not enough even to stand at the bedside with a small number of students and an instructor and listen to him talk and watch him examine, unless the individual student examines himself, not only once but many times during the course of the disease. As an illustration, the student should have abundant opportunities for feeling pulses in all kinds of sickness and in the various changes of sickness; he should learn at the bedside the significance of those changes through observation and he should after open discussion with a wise and sympathetic teacher learn to form careful conclusions; to administer himself the remedies determined on in desperate cases as well as mild cases, and to stay at the bedside and observe the results of such treatment. He should get up in the night and go to the hospital to observe changes in patients, and while there he should feel the pulse, observe temperature, examine heart, lungs, abdomen, urine, nervous systems, general appearance, whether that patient is suffering from sepsis, cardiac failure, hemorrhage, renal deficiency shock, etc., and the lessons thus learned at the bedside are not easily forgotten.

Such teaching as this I positively know is needed badly. It means much more inconvenience to teacher, student and patient, but I am certain it is worth it. We should not stop at this extra inconvenience if it will make better and safer servants of the sick. With tact and good management in the distribution of cases there would be little more objection from patients, and with the advent of university hospitals and students living near by, such bedside teaching could be carried out.

We can say that the hospital internship solves the question; but a large percentage of medical students on graduation do not see their way clear to spend one or two years in a hospital, and besides there are nothing like

and the symptom-complex cannot be explained on the theory of an accompanying bacterial infection.

The caterpillar hairs are more or less pointed, tubular structures, which are either needle-like and rigid or worm-like and flexible. Their surface is either smooth or covered with barbs or spinules. They are composed of a chitinous substance, which surrounds the medullary canal. Into this canal the secretion of the gland is emptied. The hairs are very numerous and easily detached. Owing to the fact that the barbs all point upward the hair must enter the tissues base foremost.

Formic acid, which plays such an important part in insect poison, has been proved to be present in the gland secretion (Fabre). When the hair enters the tissues more or less toxin escapes from the medullary canal, and the initial symptoms are produced. The course is chronic—may cover months or years. According to Teutschlaender,⁹ the latent period, interrupted by acute exacerbations, are so characteristic of the disease that he agrees with Meixner¹⁶ that it is almost pathognomonic for ophthalmia nodosa. Recurrences have been reported at periods of time varying from four days (Natanson's¹⁷ case) to over three years (Stargardt's⁷ case). The patient in the latter case had the first recurrence one month after the time of infection, the third attack three years later, and the fourth after another month. According to different theories, the recurrences may be owing to a new infection; the wandering of a non-encapsulated hair; or to chemical action. Hillemann,⁴ Lawford⁶ and Teutschlaender⁹ all agree that from an analysis of the clinical observations it would seem that in addition to the mechanical irritant another agent must be present, which gives to the clinical history its peculiarity, and they believe that the idea of a chemical toxic agent best explains not only the clinical manifestations of the initial attack, but is the cause of the recurrent attacks as well. The details of the process as given by Teutschlaender⁹ are as follows:

The initial inflammation subsides, some of the hairs being eliminated, while those remaining behind have their mechanico-chemical irritation hindered through the process of infiltration and encapsulation. But so long as the foreign body or its poisonous substance have not been absorbed or eliminated the process is not permanently stopped. Either there is an intensification of the poison, or else the protection of the tissue is weakened. The tissue changes, which during the inflammatory period caused a halt in the work of the etiologic factor, undergo a certain metamorphosis during the latent period. The edema and cell infiltration disappear and the protection is lessened. At the same time changes are taking place in the hair. The chitin-layer is being absorbed and larger openings in the medullary canal allow the poison to escape and the chemical agents to accumulate at the inner part of the nodule. When a sufficient amount has accumulated, or the protection is weakened or gone, an irritation is set up and the reaction appears, resulting in a recurrence of the initial process. This cycle goes on until the poison has all been carried off, when the hair remains in the tissue as an unirritating foreign body.

While the clinical picture of ophthalmia nodosa is characteristic, the anatomic changes are not. The first change is an intensely active hyperemia soon associated with round-celled infiltration which appears especially

in the direction of the foreign body and is accompanied by more or less edema. Those hairs which are superficially situated and circumscribed by the cell infiltration may be pushed out when healing follows. The mechanico-chemical action calls forth a cell diapedesis and proliferation until a sufficiently protecting wall is built up. While in the early stage of the nodule formation round-celled leucocytes are the predominating element, later epithelioid and giant cells are added.

The conjunctiva is the most frequent site of infection and it is here that the typical nodules so suggestive of tubercle are formed. The number of nodules varies greatly—in one case twenty-seven were demonstrated (de Schweinitz and Shumway⁸). They are grayish-yellow in color and between them there is marked congestion of the conjunctival and episcleral vessels.

In the cornea, the pericorneal injection appears almost immediately, and on the third day the infiltration is noticeable. While the areas of infiltration are well defined, they are not elevated as is the case in the conjunctiva and iris. This is owing to the fact that the cornea is non-vascular (Teutschlaender⁹).

The iris is far more frequently affected than the cornea. The hair perforates the cornea either through the force of the fall of the caterpillar or through the rubbing of the eye by the patient. With one part still sticking in the cornea, the hair may bridge the anterior chamber and by means of its spinules become attached to the iris, which by its movements in dilating and contracting may draw the hair away from the cornea. At the point of entrance of the hair into the iris hyperemia and swelling occur, followed by cell infiltration, resulting in the formation of a nodule. In most cases the reaction is not severe enough to jeopardize the vision, although in one reported case an iridochorioiditis plastica followed with blocking of the pupil, and in another the eyeball shrunk, resulting in phthisis bulbi.

One patient (Kruger's), as observed by Reis,¹⁸ twelve years after the occurrence of the infection, showed seven scars in the conjunctiva, one nodule in the episclera (from which a well-preserved hair was extracted), an opacity in the cornea (from which a hair was removed), and in the chorioid a Y-shaped streak of chorioidal degeneration bordered with pigment with a greenish reflex at one extremity, which Reis thought probably was a hair. The following report is of my case:

Patient.—H. S., male, aged 33, first came under observation in April, 1906, with the history of having had recurrent attacks of very severe pain and redness in the right eye at intervals of about 30 days, from October, 1905. The first attack came on with excessive lacrimation, severe pain and some swelling. After 3 or 4 days the more severe symptoms disappeared, though the eye remained irritable throughout the entire course of the affection. At this time all the history I was able to obtain was negative. Later, however, after 3 months' unsuccessful treatment, when asked if he had had anything to do with caterpillars, he replied: "Last October the caterpillars were so thick in our apple trees we had to burn them out." On closer inquiry, it was found that his first attack came on immediately after the trees had been freed of the caterpillars, but the patient himself did not associate in any way the work done on the trees with the disturbance in his eye. There was no history of having been struck in the eye, so the infection must have been from the free hairs.

Examination.—The eyelid was slightly swollen and the conjunctiva congested. With oblique illumination there could be plainly seen 5 areas of infiltration, situated in the superficial layers of the cornea. One was 1 by 3 mm. in size, running horizontally at the level of the upper pupillary margin. The other four, from 1 to 2 mm. in diameter, were situated in the

upper third of the cornea about midway between the pupillary margin and the limbus. The epithelial layer was intact, the infiltrated area apparently involving the basement membrane. The cornea between the areas of infiltration was clear except immediately adjoining the opacities where it was slightly clouded.

Treatment.—When I first saw the patient he was not suffering severely, and the possibility of caterpillar hairs being the etiologic factor did not occur to me. A careful examination did not reveal the presence of the hair, but after seeing the man in one of his acute attacks when the pain was severe, photophobia intense and the pericorneal injection marked, and the cornea had become striped about the large area of infiltration, I determined to curette the indurated areas. From the scrapings I recovered the small hair shown in Figure 1, eight months after the first attack.

Fig. 1.—Photomicrograph of hair removed from eye of author's patient. $\times 62$.

Species of Caterpillar.—In September, I asked the patient to bring me a caterpillar like those he burned out of the trees the year before. This he did, and the hair shown in Figure 2 was taken from the specimen which was classified as the *Bombyx rubi*.

Result of Treatment.—In a comparatively short time the patient was well, although some thin scars were left in the cornea at the site where the hairs were removed. As none of the scars were central his vision was unimpaired.

Fig. 2.—Normal hair of caterpillar. $\times 31$.

In the accompanying table the cases of ophthalmia nodosa are arranged chronologically. The table contains, so far as I am able to determine, all the accepted cases reported to this date.

In a majority of cases there is a history of injury to the eye by a caterpillar; in the absence of this history there is one of sudden onset of the symptoms, consisting of pain, more or less severe, much photophobia and lacrimation. These symptoms tend to subside after a few days, but do not entirely disappear. In the course of a few weeks an exacerbation of all the symptoms occurs. The time between the date of infection and the first consultation varied from four hours to six months. The period of time that elapsed between recurrent attacks varied from four days to three years.

The different tissues of the eye affected were as follows:

1. Conjunctiva: 24 cases = 62.1 per cent. of 37 cases.
2. Cornea: 18 cases = 48.6 per cent. of 37 cases.
3. Iris: 16 cases = 43.2 per cent. of 37 cases.
4. Cornea, only: 4 cases = 10.8 per cent. of 37 cases.
5. Sclera: 3 cases = 8.1 per cent. of 37 cases.
6. Episclera: 2 cases = 5.4 per cent. of 37 cases.
7. Choroid: 1 case = 2.7 per cent. of 37 cases.

In every case reported, there was either a definite history of injury with a caterpillar or the presence of a caterpillar hair was demonstrated. There was a history of injury in 27, or 73 per cent., of the cases, while the hair was demonstrated in 32, or 86.4 per cent., of the cases. The species of the offending caterpillar was determined in 16, or 50 per cent., of the cases in which the hair was found.

The following species of the caterpillar were demonstrated: *Bombyx rubi*, 10 times; the *Knethocampa processionea*, 3 times; the *Bombyx pini*, 2 times; and the spinning *bombycina* and the *Spilosoma virginica*, each, once.

The treatment adopted in the reported cases has been in the main symptomatic. The local remedies employed have been those usually prescribed in the treatment of iritis. The resemblance of the corneal lesions to those found in keratitis punctata superficialis of Fuchs has led in some cases to the administration of mercury, but without results. Operative treatment has been limited to iridectomy, to combat iritis or increased tension, and for the excision of nodules and hairs.

The prognosis in ophthalmia nodosa should be guarded. It will depend on the tissues involved, the severity of the case, and the extent of the structural change present.

I wish to acknowledge the assistance rendered me by Dr. George M. Waldeck in the preparation of this paper. (Chamber of Commerce Building.

PRIMULA DERMATITIS*

O. H. FOERSTER, M. D.
MILWAUKEE

That the primula or primrose, a flowering plant found in many homes as a floral decoration, is frequently the cause of a dermatitis of more or less severe degree, is a fact not sufficiently recognized by the medical profession.

In this country attention was first called to the poisonous property of the species of primula known as *Primula obconica*, by J. C. White¹ in 1889 and again in 1890, when several cases observed in florists were reported.² With the exception of case reports by Denston³ and Sweet,⁴ there have been no further contributions to this subject by American writers, and in the consideration of dermatitis venenata in the latest dermatologic text-books the primula is either omitted entirely or is barely mentioned. This is in marked contrast to the large number of articles on this subject which have appeared in recent years, especially in English and German medical and botanical journals. The distribution of the primula in American homes is almost universal during certain seasons, and is certainly as wide-spread as in England and on the Continent, thus giving an equal opportunity for the development of cases. The discrepancy in the number of cases reported in this country is therefore perhaps attributable to a lack of appreciation of the primula as the possible cause of some forms of dermatitis remaining grouped under the term eczema. I venture to assert that a more wide-spread knowledge of the toxic properties of this plant will shed

light on the etiology of many instances of so-called recurrent "eczema," and of cases of "mild erysipelas," basing this on my experience following the presentation of a case of primula dermatitis before a local medical society in 1903. For some time thereafter I was frequently informed by general practitioners of the discovery of cases of primula dermatitis which had masqueraded unrecognized under the convenient term of eczema, (until the primula as a possible causative factor had been brought to their attention).

My personal experience with the dermatitis produced by the primula would indicate that it is not at all infrequent, as it comprises some forty or fifty cases, of all grades of severity and extent, observed during the past seven years. In addition I have learned from others of the existence of many instances of this affection, so that I now constantly hold the primula under suspicion when inquiring into the cause of a dermatitis. In this connection the remarks of Jadassohn⁵ are very pertinent, when he says:

In the past few years the best known—but still not sufficiently well known—inflammations have been those produced by some species of the primula in individuals with an idiosyncrasy toward this plant, affecting especially the hands and face (even with iritis), constantly recurring in acute form or appearing in a more chronic manner with exacerbations. Whoever has once experienced how much an "eczema" for years always appears at a definite time, tortures the patient, is treated unsuccessfully by all possible methods, subsides on rest in bed, and immediately reappears when the patient again goes about (because the care of the plant is resumed), and finally disappears entirely after disposing of the primula, will never again forget to search for the most varied external causes in eczemas of every description.

TYPES OF PRIMULA DERMATITIS

From the observation of any considerable number of cases it is apparent that the dermatitis caused by the primula presents itself chiefly in three types, depending on the degree of idiosyncrasy. Those possessing a well-marked idiosyncrasy to the toxic principle respond with an intense inflammation, erythematous-vesicular in character, at times with the formation of bullæ, and accompanied by more or less swelling. Others develop an erythematous-vesicular or erythematous-squamous eruption of a less acute type, with considerable infiltration, after repeated attacks, and scaling continued over a long period. Again, in others an intensely itching or burning sensation confined to the pulps of the fingers, which are puffed, tense, and slightly reddened, may be the only evidence of reaction.

The clinical picture of the highly inflammatory type in all its details is well presented in the following notes from the case of a housewife, aged 58 (?) made when the attack was of sixteen hours' duration.

On the face, from level of zygoma to border of jaw, are blotchy, irregularly outlined, erythematous patches extending over cheeks and jaws, converging on the chin, but leaving nose and ears unaffected. On the central part of the left cheek is a dollar-sized patch of closely crowded, almost coalescent, peculiarly angular and flattened vesicles, with clear contents, resembling drops of dew. In the labiomental furrow and extending upward to midpoint of lower lip is an intensely erythematous and slightly puffy area with a central group of small, closely set, angular vesicles. There is no glandular enlargement. The eyelids are not affected.

The dorsum of the left hand is puffed up with an elastic, cushion-like swelling, extending to the ulnar border, over the dorsal and lateral surfaces of fingers, and slightly to the pal-

mar surface of the fingers. The swelling prevents closing of hand. A ring on the third finger is almost hidden in the fold of edema. On the dorsum and lateral surface of ring finger are three tensely filled bullæ with rounded summits and clear contents. Two bullæ are each 1 inch long and $\frac{3}{8}$ inch wide; the third is round, $\frac{3}{4}$ inch in diameter. On the dorsum of the middle finger is one bleb, $\frac{3}{4}$ inch by $\frac{3}{8}$ inch. There are no vesicles on hand or other fingers.

The dorsum of the right hand shows a pale, elastic swelling, extending over dorsum of fingers, without erythema, vesiculation, or bleb formation. The palms of both hands are unaffected, but perspire excessively.

On both forearms, more on extensor than on flexor surface, and extending upward to within two inches of elbow, is a blotchy, unevenly distributed, rose-red erythema with irregular margins, with intervening areas of normal skin. The eruption on the two arms is of equal intensity, and erythematous throughout. The remainder of the body is not involved. There is intense itching and burning, especially on lateral surface of fingers.

In other instances the reaction may be of an abortive papulo-vesicular type on an erythematous base, or simply erythematous or urticarial in character, though the latter has been very infrequent in my experience.

Primrose dermatitis, chronic type, infiltrated and scaling dermatitis.

The cases which might be termed chronic, owing to repeated attacks at short intervals, present an appearance of acute exacerbation of an infiltrated and scaling dermatitis. On the face the skin is thickened and thrown into folds, especially about the eyes, yellow-red in color and covered with closely adherent, thin scales. Vesiculation during acute attacks is imperfect and small denuded areas, slightly edematous, exude thin serum which dries into gummy, yellow crusts. The active inflammatory process appears as though focused in limited areas, without outlying reaction, and as if it were superimposed, giving an appearance of artificiality to the clinical picture, which is often quite striking.

An analysis of the cases as to age, sex, occupation, and the like, is not only of interest, but reveals some points of value in diagnosis. As the dermatitis results from direct contact with the plant it naturally follows that florists, gardeners, housewives and servants are most prominent in the list of those affected; that females are more often affected than males, and that children almost never develop the dermatitis. I observed several cases

5. Deutsch Klin., x, 146.

among the members of a religious sisterhood, and in merchants who made a hobby of cultivating flowering plants.

OCCURRENCE

The primula is hothouse-grown and its growth is forced for its sale during the holiday seasons of Christmas and Easter, though it is in the market at all times. Consequently the great majority of cases developed immediately after Easter, following the introduction of the primula into the home as a floral decoration. Others referred the beginning of the dermatitis to the period immediately following a birthday anniversary, at which time the primula had been received as a gift. In the case described earlier, the patient had been presented with a flowering primula at Easter-time for five successive years, and had promptly each time developed a dermatitis, which became increasingly severe with each recurrence. Many exacerbations followed at irregular intervals for several months, and finally the entire process ceased (after the withered plant had been removed), to reappear at the following Easter. Only once was this sequence broken, owing to the presentation of a primula on the patient's birthday and the consequent development of the dermatitis during her stay at a sanatorium, where she had gone to recuperate after several months of suffering from what was regarded as a "nervous eczema."

In another instance the dermatitis made its appearance regularly for three years on Easter Sunday afternoon, had then persisted for weeks, was considered a "gouty eczema" and was each time cured by a stay at a German health resort.

In many instances the history of regularity or periodicity of attacks or exacerbations provides the clue for determining the cause of an otherwise unexplainable dermatitis, and probably nowhere more so than in the primula dermatitis. This is well shown in the history of several cases which I have observed. One patient repeatedly developed the dermatitis shortly after every return to her own home after a period of time spent in visiting friends or traveling; her return after even a few days of absence was followed by the outbreak of a dermatitis, her first care always having been the trimming of her plants, including the primula. In another instance a dermatitis of only moderate degree and extent appeared on every successive Sunday and subsided by Thursday or Friday of the same week. This sequence is explained by the regularity with which the primula was trimmed every Friday.

The eruption is most often found on the hands, forearms, and face, including the ears, and in all of the cases observed by me these were the only parts of the body affected. I have been informed of the case of a florist in whom the erythematous-vesicular inflammation extended to the shoulders, with marked swelling of both arms.

It appears that the inflammatory reaction remains limited to those parts which come directly into contact with the plant or to which the irritating principle is transferred. Thus, in one of my cases the ears were intensely affected because of transference from the hands owing to the patient's habit of pulling at the lobes of the ears. In the case of a housemaid the fingers and wrists were the only parts affected, owing to their contact with the primulas contained in a window-box when raising or lowering the window shades. A unique case

has been reported by Kirk⁶ in which an intense swelling of the oral and pharyngeal mucous membrane resulted from chewing a leaf of the primula.

This limitation of the eruption is in marked contrast to that seen in ivy poisoning, in which areas of the skin remote from the points of original contact are frequently and severely affected.

The first symptoms usually observed are intense burning and itching, without visible change in the skin, which, however, soon responds with an erythematous blush and some swelling. I have not observed a papular eruption, though papulo-vesicles may develop later. Rarely the reaction is entirely of an urticarial nature; that is, an acute edema with serous exudate, sufficient at times to prevent closing of the hand. Small vesicles, closely grouped, develop early, and I have been impressed with the frequency with which the vesicles are angular in outline, as contrasted with the rounded vesicular lesions of eczema. The lateral surfaces of the fingers, dorsum of the hands, and the chin and cheeks show the vesicular eruption most often. In the cases I have seen the palms have always remained normal.

The subsequent course of the eruption may be acute, with the formation of blebs and considerable edema, or more subacute with rapid drying of the vesicles and scaling. The duration of a single attack may be as short as four to five days or may be extended to two weeks before recovery is complete. Acute exacerbations due to renewed exposure may prolong the affection indefinitely, and result in the production of a chronic, infiltrative type of dermatitis, lasting perhaps for several months. Fortunately, however, the discovery of the cause of the dermatitis, or the death of the plant, and consequent absence of further opportunity for renewed infection, allows recovery to take place. In this connection it is interesting to note that although under favorable conditions the primula blooms about every six weeks, it usually, after two or three months of household care, loses its vitality and is discarded, at which time the dermatitis also terminates.

The sleeplessness, anorexia, and general nervous irritability observed in some cases can be fully accounted for by the intense burning and itching which is a prominent feature of even mild types of the dermatitis. Fever, chills, joint pains, and other evidences of constitutional disturbance have never been observed by me, though transient slight rises in temperature are mentioned by Nestler.

The variation in the degree of reaction exhibited by different persons to the irritating principle contained in the primula, and the apparent immunity of others, is suggestive of the existence of an idiosyncrasy. The study of a large number of cases, however, shows in many a constantly increasing susceptibility, so that even the slightest contact with the toxic agent will eventually result in the production of an intense dermatitis. Others, apparently entirely immune, will later, after repeated exposure, develop an intense reaction just as do those who exhibit an "idiosyncrasy" primarily. Among florists and their assistants this gradual change from immunity to susceptibility is not uncommon, and I have had occasion to observe several such instances. The personal experience of Nestler,⁷ detailed in his admirable monograph, in which his immunity was finally succeeded by an intense susceptibility, provides the experimental proof for the assertion that probably no one is entirely immune.

This extremely sensitized state of the skin, causing marked reaction to even minimal amounts of the irritant, is highly suggestive of the development of an anaphylactic condition, and is comparable to the phenomena resulting after repeated introduction of essentially non-toxic sera of a different species. This view is supported by the analogous condition of increased susceptibility of the skin after repeated exposure to the dust of satinwood, with the development of a dermatitis, observed in satinwood workers by Wechselsmann.³ He also calls attention to the fact that in animal experiments parts of the phenomena of anaphylaxis occur in the skin: intense itching, hyperalgesia and spasm of the arrectores pilorum.

Individuals differ in their rapidity of response to the action of the irritant within wide limits. It has been experimentally determined (Nestler) that the dermatitis may not develop until fourteen days after contact with the plant, although the usual period is from a few hours to two or three days. After repeated attacks the response is more prompt, usually within a few hours following contact. The occasionally prolonged incubation period, and the fact that the primula dermatitis does not always appear after the first contact with the poison, but may require repeated exposures for its development, largely increase the difficulty of diagnosis.

BOTANICAL AND CHEMICAL CHARACTERS

Of the many species of the primrose family only four (*Primula obconica*, *P. sinensis*, *P. cortusoides* and *P. sieboldii*) are known to be capable of producing a dermatitis, according to Nestler's researches, and of these the *Primula obconica* is most virulent and the most frequent offender. *Primula sinensis*, the Chinese primrose, though capable of exciting an intense dermatitis, is less often in question, and will merely be mentioned here.

The *Primula obconica* was introduced into Europe from China in 1883 and several years later began to be extensively cultivated by American florists. The flowers are arranged in a whorl, borne on a slender, cylindrical, hairy stalk, and are pale lilac, pink or purplish in color. The leaves are soft, large, radical, ovate-cordate, hairy, and spring from the root. The leaf-stalk, flower-stalk and midrib are abundantly provided with coarse, easily visible hairs and innumerable fine hairs, the latter being found also on the calyx and corolla. The hairs are all glandular and exude a greenish-yellow material which forms brownish-yellow masses that are readily detached by the slightest touch.

The secretion, which contains the crystals, is readily soluble in alcohol, ether, chloroform, hydrochloric acid and sulphuric acid, but is insoluble in water (Nestler). Under the microscope the formation of monoclinic crystals can be observed.

Practically all who have written on the subject of primula dermatitis ascribe its production to an assumed mechanical irritation by the hairs of the plant, because these are pointed and said to be easily detached. My study of the subject, however, led to the conclusion that inasmuch as the hairs are not readily detached and are too soft and supple to act as mechanical irritants, the source of the dermatitis must be sought for in the secretion of the plant. The leaves have a faint aromatic odor, distinct from the perfume of the flower, and this suggests the presence of a volatile oil with toxic properties.

Experiments with the secretion applied to my skin were negative except for a temporary tingling and prickling sensation, but produced a mild reaction in a patient who had formerly experienced the dermatitis. Similar results followed the application of the dried residue left after washing a number of leaves with ether. At this time I became acquainted with the experimental work of Nestler on this subject, as detailed in his exhaustive monograph, and have been able to confirm a number of his observations. He was the first to demonstrate the existence of needle-shaped crystals and large and small rhombic prisms in the secretion exuding from and covering the glandular hairs of the leaves. By direct experiment on himself and others he was able to produce a dermatitis with crystals obtained by sublimation of the residue left after flooding the leaves with ether; he thus provides the evidence that in these crystals resides the irritating principle of the primula. Although I have repeatedly found extremely minute needle-like crystals and small rhombic forms in the ether washings and in the untreated secretion of fresh leaves, the larger rhombic formations, as described by Nestler, have thus far escaped my observation. The chemical composition of the toxic principle, however, still awaits solution. Nestler showed further that not alone the fresh leaves, but also the thoroughly dried leaves, contain the irritating substance, which explains the infection occurring particularly in housewives, who, when trimming the primula, pick off the dried leaves.

The dermatitis may develop without direct contact with the plant, owing to transference of the secretion to various objects and then to the skin. Nestler was infected several times through the medium of gloves which had been worn while experimenting with the secretion of the plant. In the case of a highly susceptible florist's assistant observed by me the dermatitis developed after handling the paper in which primulas had been packed during shipment. This mode of infection, however, is probably very infrequent, as is also the transmission of infective material from one person to another, as briefly mentioned by Nestler, and direct contact with the plant will be found to have occurred in the great majority of cases.

TREATMENT

Consequently the removal of the primula and thorough cleansing with alcohol of objects which have been in contact with the plant are required to prevent a recurrence of the dermatitis. Alcohol, ether and chloroform are solvents of the secretion, and when applied immediately after contact with the plant have been found by Nestler to prevent the development of the reaction. From my own experience I can confirm this observation, and also Nestler's statement, based on experiment, that alcohol applied immediately on the appearance of the dermatitis, in case there has been a short incubation period, results in a modified and mild course of the inflammation.

In other respects treatment is to be conducted according to the usual principles followed in cases of acute dermatitis. The intense itching and burning are usually promptly relieved on the application of calamin lotion or zinc gelatin, and under a bland ointment the inflammation rapidly subsides and the skin returns to normal after slight desquamation. This rapid subsidence of an apparently intense inflammatory process of eczematous character, under indifferent treatment, ought to be sufficient to arouse suspicion of the artificial nature

A NEW INCISION FOR EPITHELIOMA OF UPPER AND LOWER LIPS OF SAME SIDE

WALTER S. SUTTON, A.M., M.D.

Assistant Professor of Surgery, Kansas State University; Assistant Attending Surgeon, Kansas City General Hospital; Assistant Surgeon, St. Margaret's Hospital
KANSAS CITY, MO.

The incision described is an adaptation of the principles of the well-known Dowd operation to the removal of a growth involving both upper and lower lips. This readily appears from the similarly-lettered sketches presented herewith.

Fig. 1.—Suggested incision for epithelioma involving both lips.

Fig. 2.—The Dowd incision (after Binnie).

In the Dowd operation, as in its predecessor, the Malgaigne, it is usually necessary to excise a triangle (E F G Fig. 2), from the upper half of the cheek in order that the tension necessary to bring the lower flaps together may not produce a wrinkle in this location. In the absence of involvement of the upper lip this triangle may be taken out at any convenient point. If, however, there is involvement of the upper lip this triangle may be made of such size and placed in such a location as to

remove it (E F G Fig. 1). In case of a growth involving the entire lower lip and both ends of the upper lip, the procedure could be made bilateral and would then resemble the Dowd operation even more closely.

In practice the incision A B is first made and the removal of submaxillary lymph and salivary glands completed. The facial artery is preserved though its ligation is not necessarily followed by necrosis of the flap. The other incisions are then marked on the skin and rapidly completed, the outer portion of the line D H going down only to the deep fascia over the masseter. The flap A B H D is then separated from the jaw-bone as far back as required to permit the necessary stretching, care being taken not to injure the facial artery in this step. The point E is then brought over to point G and point H to point C.

Fig. 3.—Result following author's incision twenty-two days after operation.

In case of deficiency of mucosa on the part of the new-made portion of either lip, much can be done toward covering the raw area by simply drawing over the edge of the mucosa from the sound side without dissection and tacking it to the raw surface by means of one or two plain gut sutures.

Figure 3 is from a photograph of a patient in which the growth and incision lines correspond closely to conditions shown in Figure 1. The photograph was made on the twenty-second day after operation.

Argyle Building.

A CLAMP FOR ISOLATING A PORTION OF THE LUMEN OF A BLOOD-VESSEL WITHOUT STOPPING THE CIRCULATION THROUGH THE VESSEL*

G. N. STEWART, M.D.
CLEVELAND, O.

For various purposes in physiology and also in surgery it may be desirable to clamp off temporarily a longitudinal portion at one side of a blood-vessel while the circulation is allowed to go on through the remainder of the lumen. A field can thus be provided in which the operator can work at his leisure without fear of injuring the organs supplied or drained by the vessel by clamping it off altogether. I have devised a clamp by which this can be conveniently done. One form of it is shown in the accompanying illustrations.

The essential points are the following:

* From the H. K. Cushing Laboratory of Experimental Medicine, Western Reserve University.

1. The long, narrow grip of the jaws in the longitudinal direction. The grip is narrow in order that as little as possible of the lumen may be encroached on. The length of the occluded portion will, of course, vary with the purpose for which the clamp is used.

2. The extension of the grip at each end at right angles to the length of the vessel. This is necessary to complete the occlusion of the isolated segment. The length of the rectangular portions must be proportioned to the diameter of the vessel worked with. If too long, they project too far beyond the vessel, and thus make the field of operation less accessible for some purposes.

3. The hollow behind the gripping edge in which the open portion of the vessel is safely lodged and protected from pressure. The size of this hollow must be great enough to comfortably accommodate the non-occluded part of the vessel.

Fig. 1.—Front view of clamp in position on vessel; (1) middle of the isolated portion of the vessel; (2) the rectangular projections of the jaws; (3) the axis on which the jaws rotate; (4) grip for the fingers; A, open lumen of blood-vessel beyond the clamp.

Figs. 2 and 3.—Side view (to the left) of clamp (2, 3 and 4 as in Figure 1; A, open portion of lumen of vessel in the hollow of the clamp; a, occluded portion of lumen); and sectional view to the right) at position of (1) in Figure 1; (5, section of the spring through which the pressure of the clamp is obtained; a, isolated portion of the lumen; A, open portion).

In the clamp shown in the figures the pressure is obtained from a small-sized spring behind the axis. It can also be made with a screw for graduating the pressure. A pair of ordinary "bull-dog" forceps fitted with jaws of the shape described is another form which may be useful for some purposes.

Such clamps might be employed to arrest hemorrhage from a wound in a large vessel which could not be clamped completely without detriment, and during the suturing of the wound; possibly in the treatment of sacculated aneurism in some situations; in performing lateral anastomosis of blood-vessels in cases where it is undesirable to completely occlude one or both of the vessels

for the time required in the operation; in performing lateral implantation of one vessel on to another which must not be totally occluded; in inserting a cannula laterally into a vessel without stopping the circulation when there is no convenient branch of the vessel which might be used, or where it is disadvantageous to occlude such a branch; in narrowing experimentally the lumen of a vessel without temporarily occluding it, especially when a diminution of the lumen by a definite amount is desired, etc.

My colleague, Dr. George W. Crile, has told me that it might be useful to have a clamp which embodied the

Fig. 4.—Clamp to be applied to the wounded side of the vessel only.

Fig. 5.—First form of clamp as made with a screw for graduating the pressure.

principle of that just described but which could be applied over a wounded vessel without dissecting out the vessel too freely. I have therefore devised the form shown in Figure 4. This is intended to be applied to the wounded side of the vessel only. It is supposed that the surgeon could suture the wound through the open portion of the clamp while the circulation goes on through the part of the lumen not included in the

clamp. This clamp may possibly be used also for some of the other physiologic or surgical purposes for which the first form was intended. Figure 5 shows the first form of clamp as made with a screw for graduating the pressure. The jaws, of course, may be covered with thin rubber.

East Ninth Street and St. Clair Avenue.

FEMORAL HERNIA OF FALLOPIAN TUBE WITHOUT OVARY

CHARLES H. PARKES, M.D.

Assistant Professor Operative Surgery and Surgical Anatomy, Chicago Polyclinic
CHICAGO

The intention in presenting this case is not to emphasize its rarity, however unusual the condition may be, but to call attention to the possibility of the occurrence and the necessity of its recognition at time of operation.

The literature on the subject has been covered by Dr. Frank T. Andrews¹ and Dr. Paul Morf² of Chicago up to the year 1907. It is therefore unnecessary at this time, to pursue that phase of the subject to any greater extent than to refer those interested to the articles mentioned. These writers—in their reports—present cases of their own to add to the list of the few on record.

Since the publication of Dr. Andrews' last paper on the subject in 1907, very few cases are to be found; in fact, I have been unable to discover any of the femoral and only three of the inguinal variety. In these cases the tube was not found alone within the sac but with some other abdominal or pelvic viscus.

History.—The case which I wish to present, referred to me by Dr. J. F. Williams, is that of a woman 33 years old, married, whose occupation was that of a housewife. The family history is negative, having no bearing whatever on the difficulty in question. The menses began at 14, and had always been regular and without any especial pain. The patient had never noticed the occurrence of any vaginal discharge. She had been married at 30 and never had been pregnant. There was no history of injuries of enough importance to have made an impression. With the exception of an attack of typhoid fever ten years previously and the negative history of gestation and trauma, the personal history was devoid of interest.

Present Illness.—The patient complained of a small tumor in the region of Scarpa's triangle of the right thigh. This tumor had existed for about fifteen years as a small lump that varied slightly in size and consistency from time to time. It had caused no inconvenience, however, and in consequence had never been examined. Within the last twelve months the size of this tumor had increased gradually until at the time of this examination, it had reached that of an egg. During the last few days, pain had developed in the right pelvis and abdomen and the tumor itself had become tender.

Examination.—The routine examination of the patient showed her to be of large frame, with a very wide pelvis; her condition to be unusually good, except that her expression betrayed anxiety. Pulse was 110; temperature, 100 F. The tumor under consideration was situated in the right thigh, below Poupart's ligament, but a little higher than the usual location for a femoral hernia. It was tense, slightly discolored, and gave the sensation of slight fluctuation. Absolutely no impulse was obtained on hard coughing and no change in size on pressure in whatever position the leg was placed.

Bimanual examination of the pelvis revealed nothing definite because tenderness interfered with the examination. An indefinite mass could be palpated in the right pelvis. No diagnosis was made further than that of a femoral hernia, perhaps strangulated, or the possibility of an enlarged inflamed lymphatic gland.

Operation.—A transverse incision curved upward above Poupart's ligament through subcutaneous tissue to the tumor, revealed a hernial sac extending up under Poupart's ligament. The sac was thick, tense and filled with fluid. When incised, a sanguineous colored serum escaped. The sac contained, besides the fluid, what was shortly identified as about one-third of the Fallopian tube. The tube showed evidence of considerable congestion, was swollen to about the size of the patient's thumb, purplish in color and besides was adherent in several places to the peritoneum, especially around the neck of the sac. The fimbria were matted together, red, and adherent to the sac. Reduction was impossible without incising Gimbernat's ligament and even had this course been followed it would not have been warranted on account of the pathologic condition of the tube. The abdomen was incised in the median line, the general peritoneal cavity protected and the pelvis explored. The uterus was found drawn forward, twisted somewhat to the right with the cornu of that side

Femoral hernia of Fallopian tube without ovary. This illustration is reproduced from a cadaver specimen, prepared at the Chicago Polyclinic Laboratory, to show conditions found in the case.

pointing toward the femoral canal. The right ovary was discovered plastered up against the femoral ring, cystic, and about the size of an orange. The right tube was stretched, thinned and disappeared into the femoral canal. The left tube and ovary were practically normal. The indications were in favor of excision of the right tube and resection of the corresponding ovary. The tube was removed by incising elliptically into the cornu to remove mucous membrane canal in wall of uterus, suturing the uterine incision and with the same suture coapting the layers of the broad ligament outward to the femoral ring. The portion of the broad ligament which followed the tube into the sac was ligated separately; the tubal adhesions freed from the sac and the tube lifted out of the sac through the femoral incision. The femoral ring was found small and thus, by removing the tube backwards, was left small. The sac was then freed, ligated, resected and through abdominal incision, purse-stringed. The ovary was resected in the usual manner and the appendix removed because of concretions. The abdominal incision was closed and the thigh incision drained for thirty-six hours, with rubber tissue strip.

1. Andrews, Frank T.: Hernia of the Tube without the Ovary. *THE JOURNAL A. M. A.*, Nov. 25, 1905, p. 1625; Hernia of Ovary and Tube, *THE JOURNAL A. M. A.*, Nov. 24, 1906, p. 1907.

2. Morf, Paul F.: Hernia of Fallopian Tube with Hernia of Ovary, *Ann. Surg.*, March, 1910.

The patient made an uneventful recovery, leaving hospital in ten days.

When a condition as unusual as the above is encountered during an operation, the procedure must be determined by following the general principles of operative surgery, relieving the condition by removing the pathologic tissue, repairing defects and guarding against infection.

Routine methods for operating in such a case cannot be fixed, as here we have encountered the unexpected in the usually simple operation for femoral hernia.

The steps taken in this operation were determined on because of the following considerations:

1. The size of the ring under Poupart's ligament. Had this hernia been of the inguinal variety the ring could have been enlarged and a second abdominal incision would have been unnecessary.

In this case the right horn of the uterus could not have been resected through the femoral ring.

2. The fact that the tube was adherent to the sac in several places, especially around its neck; that the portion within the sac was swollen, dark red, but except at points of adhesions the peritoneum was free from blisters, erosion or anything to indicate much inflammation. This condition of strangulation was certainly mechanical rather than inflammatory and the evidences of inflammation were not of recent date.

3. The advisability of knowing the condition of the pelvic organs, especially on account of the pelvic tenderness and the mass palpable through the vagina. The median incision seems to have been justified by the finding of the large cystic ovary.

4. The superior results obtained in the removal of the tube by excising at the horn of the uterus and suturing layers of broad ligament, rather than ligating *en masse* as would have been necessary had the tube been resected in location of hernia.

5. The positive indication for the removal of the tube on account of its very evident pathologic condition.

The most plausible of several etiologic possibilities as to the causation of this condition seems to be that this was probably originally a small intestinal or omental hernia, that the abdominal contents were reducible and at some time, when reduced, were replaced by the tube. The tube was at the time, or, later, became slightly inflamed, forming adhesions between itself and the sac, causing it to become irreducible. The strangulation occurred because of the interference with the tubal return circulation, by possibly Gimbernat's ligament, with the subsequent congestion, discoloration, swelling and transudation of serum.

There may also be an explanation based on J. H. Russell's theory³ from the congenital standpoint but in this case, aside from the natural tendency to a hernia in this location, especially in the case of a woman with a particularly wide pelvis, the history containing nothing to indicate trauma of any nature, nothing here adds any conformation to the embryologic hypothesis.

If congenital it must be an accidental defect rather than a consecutive embryologic development, like that for example in the male, where the testicle descends down into the scrotum and an embryologic sac, which normally is obliterated, remains within the sheath of the spermatic cord.

The fact that this case is one in which the tube was found alone within the sac, seems to have been an accident. This should have been a case with the tube and

ovary both involved within the hernia. The ovary certainly had a tendency to follow the tube, as shown by the location in which it was found. The small hernial ring or the cystic enlargement of the ovary, or perhaps both, were responsible for its retention within the abdomen.

INTRADURAL TUMOR OF THE SPINAL CORD WITH OPERATION *

EDWARD E. MAYER, M.D., AND OTTO C. GAUB, M.D.
PITTSBURG, PA.

REPORT OF CASE AND ANALYSIS BY DR. MAYER

The diagnosis of tumors of the spinal cord is no longer difficult, nor is their operability in a majority of cases a debatable question. Indeed the large number of patients successfully operated on has fully justified the optimism of Victor Horsley as expressed by him three decades ago.

Fig. 1.—Patient with intradural tumor of the spinal cord, front view, showing areas of anesthesia, hypesthesia, and normal sensation; from photograph made four months after operation.

Fig. 2.—Same patient, back view, showing areas of lessened sensation, lost sensation, and normal sensation in spots; from photograph made four months after operation.

Since then in every country many have contributed to our knowledge of tumors of the spinal cord—the recent books of Malaise, Bruns, Oppenheim and Schlesinger covering well the entire subject—so that we shall try to avoid being too discursive.

3. Russell, R. Hamilton: Congenital Origin of Hernia, *International Med. Jour.*, Australia, Jan. 20, 1906.

* Read in the Section on Nervous and Mental Diseases of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

CASE REPORT

Clinical History.—July 12, 1909. Family and previous history are not noteworthy. The patient, M. T., had not had syphilis, gonorrhea, or any infectious disease, but probably did overexert himself and subject himself to cold and privation. A cloth manufacturer in Russia, he was reduced to poverty, and for some years after coming to America peddled, carrying a fifty-pound grip. For the last four years he had been a store-keeper in a small way.

Present Illness.—In 1904 he felt a slight pain between his shoulder-blades. This was continuous for about one month and was especially noticeable when he threw his head back or turned his neck; when recumbent he could move head and neck freely without any pain manifesting itself. This pain grew worse, was intermittent, and would shoot down the inner side of his arms, and at one time disappeared for over a year. In October, 1908, on the advice of his physician, he went to Mount Clemens to try to get relief there from this pain. At this time he could not stoop to tie his shoe laces on account of the pain in his neck. His spine was at no time stiff, however, nor was there any lateral deviation or torticollis. When he would sit for any length of time, a numb feeling would steal up his legs which he would not notice when he was standing or walking. Later, a similar sensation developed around his right elbow. Pain between his shoulder blades not only persisted, but now

also in the ulnar side. He had no erection and no ejaculation for six months, nor had he any longer control of either bladder or bowel. When he wished to cough or take a deep breath he felt a constriction or sense of heaviness across his chest. The patient slept soundly except when awakened by the spasms. There was no disturbance of hearing, smell, taste or of speech. There was absolute paralysis of lower limbs, with pronounced clonus, and incontinence of urine and feces.

Right Hand and Forearm: Weakened power of supination; no power for extension of hand; inability to flex fingers completely. He could flex second phalanges about thirty degrees. There was inability to abduct thumb; slight abduction and adduction of fingers on radial side; absent on ulnar side. Interosseal and intrinsic hand muscles were slightly atrophied. Hand grasp was zero.

Left Hand and Forearm: Extension and flexion weakened but neither so much as on right side; abduction of fingers weakened; hand grasp zero.

Reflexes: Mendel-Bechterew phenomenon present; knee-jerks both much increased; Babinski present in both legs; Oppenheim present in both legs; Gordon present in both legs; cremasteric reflex, faint; abdominal reflexes, absent; triceps and ulnar reflexes, diminished; scapular reflex, absent. On extreme lateral movements of eyeballs there were slight nystagmoid movements. Right pupil slightly larger than left.

Fig. 3.—Diagrams of sensation areas in same patient before operation. In A A, area covered with crosses indicates loss of temperature sense to both heat and cold; stippled area indicates deficient temperature sense, either delayed or not always correctly interpreted. In B B, stippled portion indicates the region in which both pain and tactile senses are lost; portion shaded with lines indicates additional area with tactile anesthesia; solid shaded portion in hands represents lost muscle sensation.

would not stop when he was walking or when recumbent or with any position of his head. While at Mount Clemens, he took the baths and massage and believes his pains disappeared for a few weeks. However, he returned home very weak, and a little later, (November, 1908,) noticed a weakness in his right leg which could not be lifted as easily as before. This grew worse from day to day. About a month later, his right arm began to feel heavy and his hand-grasp was weaker than formerly. This weakness increased to paralysis. About January, 1909, his left leg and arm became involved similarly. He came to see me on January 11, was told of the seriousness of his condition and the probabilities of an operation, and advised to go immediately to the hospital. He chose to be guided by other opinions, however, and presented himself again only on July 12, six months later.

Examination.—At this date the patient was absolutely helpless, having been bedridden from the beginning of March. He complained very much of cramp in his calf muscles, accompanied by involuntary flexion of his legs, with sharp pains extending up his arms and back, to his neck. He had absolutely no power of voluntary motion in his lower limbs. When his lower limbs contracted involuntarily, his fingers drew up

Normal pupillary reactions. Equal palpebral fissures. Fundi normal. Normal neck and shoulder movements. No enlargements of vertebrae. Entire spinal column freely movable. Percussion, which was taken with posterior surface of the flexed index-finger elicited slight tenderness over sixth cervical vertebra. Auscultation with percussion (tonal percussion) over vertebrae negative.

Sensation: Patient complained of a cold pain in right leg. In areas of lost sensibility, patient felt at some places a delayed sense of touch or pain without being able to orient it; that is, to tell where he had felt it. This was most noticeable in the lumbar flanks and inguinal region. Lost tactile sensation extended one segment higher than lost pain sensation, as high as the second rib in front and the first dorsal vertebra behind. Temperature sense was disturbed about equally in areas shown by chart, but especially on the right side of the body. Inner side of arms anesthetic, analgesic and thermaesthetic; bathyanesthesia and pallanesthesia of both lower limbs.

Wassermann negative; von Pirquet negative; blood examination negative; radiograph negative.

Diagnosis.—Tumor involving seventh and eighth cervical and first thoracic spinal nerves, the sensory changes pointing especially to the eighth cervical and first thoracic, and the muscle changes to the sixth and seventh roots as well. Operation was not arranged for until September on account of taking our vacation.

This history on analysis read so clearly that a diagnosis of spinal cord tumor was easily made, its location, structure and extent only requiring a further study. It is needless to emphasize the importance of establishing these points in discussing the question of a spinal tumor and its operability, which carry with them a consideration of the segments of cord or of spinal roots involved. I am omitting all special points connected with tumors of the vertebrae themselves, or of intramedullary tumors, except as they enter into the question of the diagnosis of intravertebral tumors, extradural or intradural, which are primarily the operable types, and whose clinical histories are practically similar. It is to the intradural variety that this case belongs.

SYMPTOMS AND DIAGNOSIS OF INTRADURAL TUMORS

Symptoms of intradural tumors, following somewhat the arrangement of Bruns may be grouped as follows:

1. Spinal Roots:
 - a. Irritative symptoms.
 - b. Compression symptoms.
 - c. Atrophic symptoms.
2. Spinal Cord:
 - a. Symptoms of local pressure.
 - b. Symptoms of tract disease:
 1. Unilateral.
 2. Bilateral.
 - c. Symptoms due to growth of tumor into cord.
3. Vertebral:
 - a. Erosion.
 - b. Trophic.

In other words, depending on the origin, size, and manner of growth, intradural tumors will slowly but progressively evoke symptoms of unilateral, later bilateral, pain and hyperesthesia, radicular in type, spasms and then paralysis, perhaps of a Brown-Séquard type at first (unilateral compression of cord), but generally becoming rapidly a paraplegia (total compression) with atrophy.

With Mr. T. no objective early history was obtainable, but even his meager description brings out a very important fact; that is, the fairly constant pain between his shoulder-blades was made worse on movement. Though there are exceptions, whenever an algia of such a location is intensified by movement of the head or by stooping, coughing, etc., a strong suspicion of spinal root irritation should be instantly created. Indeed, if at that time, it had been found on examination that the algia extended segmentally, and not according to a peripheral innervation, with the absence of any lateral deviation of the spine or stiffness, a probable diagnosis of spinal cord tumor at that time, even before the onset of any paresis atrophy or segmentary anesthesia, would, I believe, have been justifiable. The necessity of examining for objective sensory changes twice a month or oftener, is also indicated, in order to detect the oncoming of this significant diagnostic point. The occurrence of edema in the innervation zone of the painful spinal root, to which Schlesinger and, lately, Pease and Bailey call attention, is a valuable help when present. With doubtful pains, corsets and braces or extension are advocated, though Oppenheim calls attention to their making the symptoms rapidly worse. The question of an eccentric projection of pain (Shultze) should never be forgotten, and all possible diseases of the thoracic and abdominal organs excluded. An extension upward of a spinal growth would

of course, involve new segments and roots and evoke symptoms higher up the cord. An extension downward need not cause any new symptoms; never, if there has been a complete conductive paralysis. A bilateral pain is more often found in vertebral tumors than in tumors of the roots and spinal cord, and if in addition shortening of the spinal column is noticed, carcinoma of the vertebrae is most probable. Of course, the incomplete intercostal neuralgias which are not of Head's type, found in hysteria and the presence of trophic muscular disturbances accompanying simple chronic neuritis, must always be excluded.

The fact that three nerve roots must be affected before distinct sensory and motor paralysis occurs emphasizes in my opinion the importance of a careful investigation of these prodromic symptoms of spinal root irritation, their intensity, constancy and stubbornness to medical treatment, their aggravation on movement and explosive respiratory acts, the segmental character of the pain and tenderness or hypesthesia present and possibly localized tenderness or increased pain on pressure over vertebrae. A change in the vertebral percussion note manifestly could occur only late in the growth of the tumor (except of the vertebral tumors), and if it did occur early, should awaken suspicion of a serous meningitis more than of tumor. The change, however, in the percussion note is so slight that it can never be of much value as a diagnostic factor. Palpation and percussion should always be done slightly to each side of the spinous processes and in palpation I have found that pressure upward helps to get a more reliable result. Percussion on one side and listening with the stethoscope on the other side of the spinal column is a good method.

A striking point in our patient's history is the length of his period of pain. Though the course of spinal cord tumors is a slow one, and of the intradural type the slowest (an average of twenty-six months according to the most reliable statistics), with Mr. T. we have a history of four to five years of radicular pains, indicating possibly an irritative state before the appearance of, or without an increase in the size of, the tumor. The question, moreover, of a possible primary radicular disease preceding the growth of the tumor, must be considered. Such a protracted course is, however, not exceptional as the histories given by Horsley, Bruns and Oppenheim show, though in our patient it persisted longer than in the patients reported by them before compression symptoms developed. I could hardly reconcile this slow course with the pathologic finding of an endothelioma.

We have learned from experience that motor symptoms without sensory alterations, even though they increase progressively, cannot be accepted as conclusive evidence of the presence of a tumor of the spinal cord, and that whenever there is reasonable certainty of its presence, the place for operation depends on the localization of the upper pole of the growth. Charting on the skin the areas which show sensory alterations is without question necessary in every case of spinal cord disease, and especially in suspected tumor cases. Further realizing that every muscle and skin area is innervated by from two to four segments, we must locate the seat of cord injury at least one segment higher than the paralysis of motion and sensation indicates. I have, for instance, at present in my service at the South Side Hospital a probable case of dorsal-cord tumor in which the motor paralysis is of the second to the fourth lumbar segments and where the upper pole of the hypesthesia is at the

level of the tenth dorsal vertebra. Operation will be justified, however, a little higher, as it is reasonably sure that the seat of trouble is higher. The pains and spasms of this patient are particularly prominent and call attention to the importance of such symptoms in localizing the upper pole of the growth. Indeed, where this so-called *anesthesia dolorosa*, or the so-called *paraplegia dolorosa* of Cruvelhier, is present, its value for localization exceeds every other symptom. Though therefore in this latter patient we would from her paralytic symptoms view her paralysis as lumbar, the hyperesthesia and spasms point to a higher innervation and must be considered in the operation to be performed on her.* Another interesting symptom of this patient is the intermittent presence of Babinski's sign, present one day, absent the next.

Unless the surgeon is also a neurologist, he should always have the seat of injury or of disease thoroughly located, if possible, before operation. I was, for instance, recently asked to examine a patient because he did not recover motion and sensation after a laminectomy; in him I found segmental symptoms several segments higher than the operative site, though I could not assert, not having examined him previously to the operation, that there had not been an ascending myelitis since the operation. How much better, however, had it been if this patient had been thoroughly examined before operation!

To return to our patient who is the subject of this paper: The sensory charts revealed an involvement of the last cervical and upper dorsal segments. We assumed the upper pole of the growth to be a little higher, because of the total anesthesia and paralysis, and because of the local tenderness ignored the dorsal cord entirely, and the operation, skilfully performed by Dr. Gaub, revealed a tumor at the sixth cervical segment. I wish to also add that Drs. McKennan, Diller, Henniger and Silver saw this patient and confirmed our diagnosis.

One cannot too strongly remember that to have paralysis, two or three spinal roots or segments must be injured, and that with an area of intense pain the spinal root above, or perhaps two spinal roots, are probably affected. Individual variations of course occur, so that whenever we have hyperesthesia lying segmentarily over an anesthetic zone, it clinches localization. In segmental localization the upper pole of the lesion is always higher than the symptoms indicate and often higher than the area laid bare by the surgeon. That the innervation zones are given by some authorities a segment higher or lower than generally accepted can be practically ignored, because of the rarity of such an occurrence, coupled with the fact that we must, on account of the trisegmental innervation spoken of before, and of the topographic relations of cord, roots and vertebrae, allow for an error of at least one segment. I am not forgetting that dissociated anesthesia as a temporary symptom has been occasionally reported even in extradural tumor, but it is an extremely rare occurrence.

Given a positive segmental diagnosis in any progressive disease where the pains are severe and there is no hope for any other kind of benefit, operation, in spinal cases, is indicated (except where gliosis symptoms are present), even where the diagnosis is not clear, and subacute myelitis, localized serous meningitis or pachymeningitis have not been absolutely excluded.

Postoperative History.—The damage to the cord in our case was too extensive to warrant absolute recovery, though Mr. T. is better and his life has been saved. Loss of sensation gradually decreased to a hypesthesia on the right side and his spastic phenomena measurably decreased in intensity, but not entirely. Both motion and sensation gradually improved in his left arm and hand, but not in his right, and he can now turn in bed, partially sit up and move his toes, all of which was impossible for him to do last summer. The last sensory chart made of him shows that his thermic sense has practically become normal on his right side; that the upper level of the hypesthesia is not as high as was the anesthesia (right side), but practically the same on the left side. His right hand remains totally paralyzed. Notes made by my assistant, Dr. MacIntire, this spring read:

"Right Arm: Partial abduction of wrist. No abduction. Palmaris longus causes flexion of wrist. Slight contraction of flexor sublimis digitorum seen in movements of index finger only. Spade-like hand. Thenar and hypothenar eminences atrophied. Pronation and supination normal. No lateral movements of fingers or of thumb. Left Arm and Hand: All muscles normal."

The pictures taken by Dr. MacIntire show the present sensory involvement. A last report from our patient informs us that he now sits up ten hours daily and sleeps soundly all night, his obstipation being what most troubles him at present.

REPORT OF OPERATION BY DR. GAUB

The patient was placed in the prone position, with the head slightly lower than the shoulders, which eliminated the normal curvature of the posterior surface of the neck.

A straight incision was made over the spinous processes of the vertebrae, beginning at the fourth and ending at the first dorsal spinous process. The soft tissues were removed from the spinous processes and lamina of the fifth, sixth and seventh cervical vertebrae.

The arches of the sixth and seventh cervical vertebrae were removed by means of Macewen's bone-cutting forceps. Nothing abnormal was found. The dura presented a normal appearance and pulsated.

At the suggestion of Dr. Mayer the arch of the fifth cervical vertebra was removed. The dura was opened in the median line, revealing the cord, whose contour showed no gross alteration.

The exposed cord, at its lower level, felt resistant on palpation. By means of an aneurism needle the cord was gently drawn to the left, which exposed a mass the size of a Malaga grape, bluish white in color, situated on the right anterolateral surface of the cord, apparently traversed on its posterior surface by the posterior root, on account of the dislocation of the cord, and on blunt dissection it seemed to surround the anterior root of the sixth cervical nerve.

During the process of removal the tumor ruptured, but with care it was removed, possibly with the exception of a minute portion of the growth, which may have remained in the sixth intervertebral foramina.

The tumor on microscopic examination, made by Dr. Proecher, pathologist to the Allegheny General Hospital, proved to be an endothelioma. The dura was closed with interrupted catgut sutures, the soft structures, as far as possible, coaptated by means of a continuous catgut suture, and the intermuscular space drained with rubber tissue.

The patient was placed in bed on his side. There was moderate shock. Within a few hours, the temperature rose to 102.6 F. and continued a degree lower, with slight remissions, for the next seven days. There was moderate leakage of cerebrospinal fluid. After the removal of the drain, the patient suffered a chill and a rise in temperature to 103.2 F.

The temperature dropped to normal within thirty-six hours. It continued at 99 F. for a week, when there occurred a second chill, moderate in severity, and a rise in temperature to 101 F. This quickly subsided and the temperature remained around 99 F., until four days later there was another chill and the temperature arose to 102.6 F., which again quickly receded.

Two more chills, mild in character, and an increase in temperature occurred at intervals of four days, following which the temperature remained normal.

* Since this was written, an operation on this patient was performed and no tumor but a localized meningitis was found.

Diagnosis.—Tumor involving seventh and eighth cervical and first thoracic spinal nerves, the sensory changes pointing especially to the eighth cervical and first thoracic, and the muscle changes to the sixth and seventh roots as well. Operation was not arranged for until September on account of taking our vacation.

This history on analysis read so clearly that a diagnosis of spinal cord tumor was easily made, its location, structure and extent only requiring a further study. It is needless to emphasize the importance of establishing these points in discussing the question of a spinal tumor and its operability, which carry with them a consideration of the segments of cord or of spinal roots involved. I am omitting all special points connected with tumors of the vertebrae themselves, or of intramedullary tumors, except as they enter into the question of the diagnosis of intravertebral tumors, extradural or intradural, which are primarily the operable types, and whose clinical histories are practically similar. It is to the intradural variety that this case belongs.

SYMPTOMS AND DIAGNOSIS OF INTRADURAL TUMORS

Symptoms of intradural tumors, following somewhat the arrangement of Bruns may be grouped as follows:

1. Spinal Roots:
 - a. Irritative symptoms.
 - b. Compression symptoms.
 - c. Atrophic symptoms.
2. Spinal Cord:
 - a. Symptoms of local pressure.
 - b. Symptoms of tract disease:

I have, for instance, at present in my service at the South Side Hospital a probable case of dorsal-cord tumor in which the motor paralysis is of the second to the fourth lumbar segments and where the upper pole of the hypesthesia is at the

UNIVERSITY MEDICAL SCHOOLS *

JAMES J. WALSH, M.D., PH.D., LL.D.

Dean and Professor of the History of Medicine and of Nervous Diseases at Fordham University School of Medicine

NEW YORK

• In recent years there has been a very decided improvement in medical education in the United States. It is not hard to understand why the foreigner lifts his eyebrow in surprise when he is told that most of our medical schools a generation or two ago required but two terms of four or five months each and that there was just beginning to be a demand for a little more complete course and better facilities. There were many medical schools with these low standards turning out graduates every year with the degree of Doctor of Medicine, which constituted a license to practice in every state in the Union, for there were no laws regulating the practice of medicine. As for preliminary requirements, the less said the better. If a man could write his name—and, indeed, he did not have to write it very plainly—he found it easy to matriculate in a medical school and to be graduated at the end of two scant terms. He might come from the mines or from the farm, or from before the mast, or from the smithy, or the carpenter shop; he need know nothing of chemistry, or physics, or botany, or English, or, above all, English grammar, to be admitted to what was called a professional school and graduated when he had served his time. Practically no one was “plucked.” The desire of the faculty for numbers of students forbade that in most cases. The two terms in medicine were not even successive courses. The second-year student listened to the same lectures that he might have heard the preceding year.

We all know the reason now for this extremely low standard of medical education. Proprietary medical schools made it their one business in life to make just as much out of medical education as possible and the professors, or sometimes the dean, pocketed the fees—I came near saying the spoils—every year, and robbed medical education of whatever possibilities it might have for the real training of young men in the science and art and practice of medicine. Perhaps the most interesting feature of this maintenance of extremely low standards in medical education is the fact that, in spite of it, men—at least many of them—succeeded in obtaining a good foundation in medicine and then, by personal work afterward, came to be excellent practitioners of medicine. Professor Welch said not long since:

One can decry the system of those days, the inadequate preliminary requirements—the short courses, the dominance of the didactic lecture, the meager appliances for demonstrative and practical instruction, but the results were better than the system. Our teachers were men of fine character devoted to their duties; they inspired us with enthusiasm, interest in our studies and hard work, and they imparted to us sound traditions of our profession.

Some of these very admirable results our medical schools with their longer terms do not achieve at the present time.

Nothing that I know is a better testimony to American enterprise and power of overcoming the difficulties of an almost impossible situation than the life-stories of some of the men who came from these utterly inadequate schools. If with the maimed training and incomplete education given a generation ago American medicine not only succeeded in maintaining the dignity of

the profession to a noteworthy degree, but also raised up many men who made distinct contributions to world medicine, what may we not do now that our medical education is gradually being lifted up out of the slough of despond in which it was, and the preliminary education for medical students set at a standard where real work can be looked for of thoroughly scientific character from the very beginning of the medical course?

Is it any wonder, then, that those of us who have the best interests of American medicine at heart are watching with deep interest the movement that is now reforming medical education in this country? The one hope of medical education is and always has been organic connection with the university. Real university medical schools—that is, medical schools as the genuine post-graduate departments of universities with the fine training that they give—have opened our eyes to what is needed in medical education in this country. Some of the old-time medical schools here in the United States had been connected by name with universities; but this connection was more apparent than real, and the medical faculty ruled absolutely in its own department, throttled medical education, and divided the income of the college among themselves, devoting as little as possible to equipment, to laboratories, to all that was needed for medical education.

Now has come the epoch of university medical schools in this country—I came near saying America; but we must not forget that the Spanish-American countries having adopted their educational systems from their mother Latin country always maintained the organic connection of the medical schools with their universities, and as a consequence a good preliminary education has always been required there. At least four years in the medical school were required even in the sixteenth and seventeenth centuries, and five and six years during the nineteenth century in all these Spanish-American countries. I have thought, then, that this story of medical education in connection with universities and genuine university work would be interesting to the graduates of that great western university whose work in medicine is acknowledged to be up to the best standards of university professional work, and whose organic connection with a great university assures not only a continuance, but the future development of medical education here along lines that shall place this in the very near future among the productive medical schools of the world.

The first university medical school that well deserves that name is the one that came into existence in connection with the University of Alexandria. I have been at some pains, because it is so delightfully amusing, to point out how the University of Alexandria resembles our modern universities in most particulars. It was founded by a great conqueror who had gone out and made the world his oyster, and, having extracted from it the pearl of supreme dominance, sighed for more worlds to conquer, founded a great city that was to be the capital of his empire, and looked forward to endowing a great institution of learning in that capital that was to attract students from all over the world. When he died prematurely the Ptolemies carried out his wishes. Money was no object at Alexandria; they put up magnificent buildings, founded a great library, bought a lot of first editions of books in the shape of original manuscripts, stole the archives of Athens, used Alexander's collection made for Aristotle as the foundation of what we would call a museum, paid professors better salaries than they received anywhere else, and housed them in

* Address to the graduates of St. Louis University Medical and Dental Schools, May 31, 1910.

twenty years. Before that their courses were brief and unworthy and no preliminary education was required.

The universities of Spanish America from the very beginning required three years of preliminary training in the university before medicine could be taken up, and then four years of medical study. These four years became five and six years in certain countries, and at no time during the nineteenth century did the medical education of Spanish America sink to the low level unfortunately reached in the United States. The lesson of it is clear. When medical education is seriously undertaken as a university department all is well. When it is not, results are disastrous.

887 Longwood Avenue.

THE PREVENTION OF INFANT MORTALITY FROM AN EDUCATIONAL STANDPOINT*

L. T. ROYSTER, M.D.,
NORFOLK, VA.

In no line of research has scientific investigation achieved more striking results than in medicine. Nor has the broad-mindedness of the physician been content with the mere alleviation of human suffering, however praiseworthy this may be, but that altruism which has characterized the profession is impelling it to

with ever-widening success for the complete eradication of preventable disease and suffering and the developing of a race noted for health, vigor and strength. Preeminent among such efforts stand the investigations of the pediatricists, who hold an undisputed position among the pioneers in the study of prevention, and I may safely say that enough is known to-day to reduce materially the present fearful rate of infant mortality if the knowledge were properly applied, and yet with all that has been discovered and the knowledge which has been acquired, the actual number of deaths during infancy has not been materially decreased, and the question naturally arises, why? The answer is simple; because a knowledge of the means of preventing infant mortality has not been sufficiently disseminated among the people. If this is true and I am thoroughly convinced that it is true the question resolves itself into the best means of distributing such information as will aid in this campaign, to all people of all classes and conditions of life, showing them what are the causes of mortality, the results of bad management and how best to apply the knowledge of the means of prevention to the accomplishment of the desired end.

I propose, therefore, to discuss a few ways in which education may aid in a material reduction of the death-rate among infants and children. It seems to me to be entirely proper that we start with the profession itself in our campaign of education, for on us must rest the burden of at least interesting the public in the vast importance of this crusade and directing its mind in the right channel along which to work.

In the first place, the course in pediatrics in the majority of colleges is entirely inadequate and far from commensurate with the importance of the subject. Anatomy, practice of medicine, therapeutics, materia medica and other branches are well taught in the average medical college and even a certain number of actual deliveries in obstetrics are required for graduation; and, as is well known, surgery is given so much time both in

lecture and in attendance on clinics that one might well imagine that nine-tenths of all students who graduate are being prepared for a practice wholly devoted to this branch, whereas, in many colleges, if pediatrics is taught at all, it is treated as an unimportant side-branch of practice of medicine or obstetrics. It would appear, therefore, that the college authorities fail to realize the importance of the subject, which is important to the student because it is a very necessary part of his preparation for general practice into which the majority of the graduates of the medical schools fall, and important for its bearing on the life and health of the nation, for mortality among infants means not only depopulation but deprivation of many useful, if not wealth-producing citizens to the community; while morbidity—which cannot be separated from mortality in such a discussion as this—bears directly on the virility of the race. So in the beginning I must make a plea for better instruction in this branch of medicine during the college course.

One of the most serious matters for consideration is the awakening of the practicing physician to the vast importance of the proper handling of infants and children, for barring the three great factors, poverty, overcrowding and ignorance, all more or less economic in their nature, the careless or ignorant physician is perhaps the most difficult part of the problem to handle. Many doctors are either too ignorant or too lazy to attend properly to the needs of infants during the first year of life; consequently they turn these helpless creatures, especially the artificially fed ones, over to a nurse who may or may not know anything about their care, or what is worse, dismiss the case with the sole instruction to an ignorant mother to put the child on A's or B's patent food and to follow the manufacturer's circular; or else to employ the equally vicious alternative, condensed milk. Some one has aptly said that "the patent food is the boon of the lazy doctor, the bane of the suffering infant," and I know of no words which better describe the situation. Such men as these are either unwilling to admit that they do not know how to feed infants or they are afraid of losing a few dollars by referring the case to some one competent to take charge; and are comparable to the obstetrician who fails to instill the silver solution into the eyes of the new-born.

As I have stated, this class of physicians presents an exceedingly difficult phase of the problem and I am quite certain that there is only one way in which they can be reached and that is through their patients. The public must be taught wherein consists proper and improper handling of infants, what constitutes good feeding, the evils of improper feeding, and in a general way, what is right for the physician to do. When they understand these things, as they will in a remarkably short time, if properly instructed, they will then demand more careful and approved attention to their children on the part of the family physician, who will be compelled either to study approved methods for himself or to seek aid from those better informed on the subject. Likewise the people should be taught the true significance of the blindness resulting from the gonococcus and the means of its prevention, and when they fully realize its importance we can rely on them to see that the attending obstetrician or midwife uses the silver solution.

As we all know, the most important and far-reaching of the many causes of the condition under discussion is ignorance on the part of those having the intimate care of children during that most critical period of life—infancy. This, of course, usually means ignorance on the part of mothers; hence the key-note of the whole

* Read in the Section on Diseases of Children of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

situation is the education of the mother in the home. When taking histories it is not an uncommon occurrence for a mother to state that she has had seven or eight children and that she has raised only one or two, the rest dying in infancy. This, in the majority of instances, is the most striking commentary on the knowledge (or ignorance) of the mother. Nor is this to be wondered at. Many a woman becomes a wife and subsequently a mother without having had instruction in any of the many difficulties with which she is to be confronted, with the natural consequence that she is soon surrounded by a galaxy of sympathizing and self-opinionated neighbors who are pouring into her open ears a detailed account of miraculous cures effected by this or that remedy, which she receives and uses with an avidity born of desperation and bred of the ignorance of which she is the unfortunate heir. As the natural result of this the stricken mother has the misfortune to see her offspring wilt in her arms, where she invariably keeps it, until at last the physician may be called only in time in most cases to sign the death certificate. The influence of "grannies" is gradually passing, at least among the better classes of society, and yet their superstitions are still apparent in many of the so-called home remedies in common use. The fear of fresh air for the well, to say nothing of the sick infant (especially those sick with eruptive diseases) is still so prevalent as to make us involuntarily ask the question whether the value of fresh air has even begun to be appreciated by most people; while the methods of feeding and handling which are generally practiced are so obviously indicative of ignorance that we might well imagine we are dealing with mothers just from the African jungle rather than in the heart of American civilization.

I am glad to see that the custom of early weaning from the mother's breast is rapidly going out of fashion; but the importance of maternal feeding as a factor in the prevention of infant mortality cannot be impressed too strongly on the popular mind. The economic value of breast-feeding should be emphasized, and will appeal strongly to those of moderate means. About nine out of every ten mothers who come to my clinic (mostly negroes) know of only one substitute for mothers' milk, and that is condensed milk; and when told of the value of fresh cows' milk at once inform us that they know of no one who has just one cow from which to secure the child's food. So deeply does this idea of the one cow's milk for the child seem to be implanted in the minds of the poorer people that it is with great difficulty they can be persuaded to get their milk from a good dairy or the milk laboratory. These ideas and superstitions are in many instances so well established in the popular mind that when we endeavor to explain the correct method of procedure, we often meet with such a degree of suspicion toward the physician that it would appear the profession is held in light esteem and that its opinions are regarded with less confidence than those of the old women or neighbors alluded to before. Hence the confidence of the people must be secured to the physician before much can be accomplished.

It is well known what remarkable success has met the efforts of those interested in the prevention of tuberculosis in instructing the public concerning the cause, means of prevention and cure of this disease through the medium of a general educational campaign; why then cannot as much be done through the same means in the equally important field of the prevention of infant mortality? As has been said before, the key-note of the situation is the education of the mother in the home.

How then may we best reach the mother? A great deal can be done through popular lectures and magazine articles and the few such articles as have appeared in some of the prominent magazines have already borne fruit, as I have had opportunity to witness quite recently; and such articles have greater weight than the private talk of the family physician, or else confirm what he has often said and prove the correctness of his statements because it has been "seen in print."

Probably the greater proportion of mothers, however, never see these magazines or hear a popular lecture and the valuable information contained in them is lost to the most important part of the population. This class, therefore, is to be reached through other channels and I know of no better way than through the well-conducted dispensary and milk depot. The instruction and advice given in the dispensary can be followed up in the home by a competent visiting nurse, without which any dispensary or milk depot is seriously handicapped, if not a failure, so far as popular education is concerned. Whatever the method, therefore, whether by magazine article, pamphlet, dispensary or the individual instruction by the visiting nurse in the home, the object should always be to gain the confidence of the people so that they will follow the advice and instruction of the physician or nurse rather than of the self-constituted and ignorant adviser or the patent-medicine circular.

The havoc wrought by long working hours for the nursing mother and the woman about to become a mother are too well known to physicians to be more than mentioned here, but not until the public generally becomes aware of this injury to women and its fearful results to their offspring in mortality and morbidity, shall we ever secure a proper regulation of labor laws. I believe, firmly, that when public sentiment is sufficiently aroused, the people will demand of both legislator and manufacturer regulation in this matter and a respect for life and health as opposed to the value of the dollar. Human life and health, however, can be shown to be a valuable asset of pecuniary value and, when this is done an impetus will be given the struggle for regulation of working hours which cannot be secured in any other way, for we all know what a powerful influence the monetary standard of valuation possesses. From this point of view, I have strong hope in the aid we shall eventually receive from the insurance companies, especially those of an industrial nature; for when these companies once fully appreciate the relation between the health of the pregnant woman and her unborn offspring and the insurance risk of the child or man, when insured at a later date, I am confident that we shall then have to aid us both the moral and the financial influence of these great powers.

The signs of the times already point to bettered conditions now or in the very near future, and the press, from which we are to hope for the greatest assistance in this matter, is alert to the importance of the question as is shown by a comment in the *Chicago Record-Herald*, in reporting a recent legal decision bearing on this matter. The comment reads:

What we know as men, we cannot profess to be ignorant of as judges. . . . As weakly and sickly women cannot be the mothers of vigorous children, it is of the greatest importance to the public that the state take such measures as may be necessary to protect its women from the consequences induced by long, continuous manual labor in those occupations which tend to break them down physically. It would therefore seem obvious that legislation, which limits the number of hours which women shall be permitted to work to ten hours in a single day, in such employments as are carried on in mechanical

establishments, factories, and laundries, would tend to preserve the health of women and insure the production of vigorous offspring by them and would directly conduce to the health, morals and general welfare of the public, and that such legislation would fall clearly within the police power of the state.

There is another field of usefulness in this educational effort which has been touched on but sparsely in the literature at my command, but which appeals to me most strongly since, being in touch with primary education, I see its possibilities, and this is the public school. Hygiene is taught in the school in a general way, hygiene of the home and public hygiene, but the hygiene of early life, that which bears directly on the life and health of the infant is neglected. The girls of our schools to-day are not only the mothers of a short generation hence, but many are the "little mothers" of the poor at present. Why should they not be taught the care of the child and the general principles of feeding? The only reason is that its importance has not been sufficiently recognized. Some effort has been made in this direction in the playgrounds under the teaching of the caretakers there employed; but this instruction has not been taken directly into the schools. We all know the powerful influence of whatever is taught in the schools and the rapidity with which the pupil carries the lesson into the home and how reflexly the parent is influenced by the child's knowledge. Why should such an opportunity as is here afforded to spread information regarding the care of the infant be allowed to pass? This is especially important among the foreign element which grasps with such remarkable avidity anything which looks like improvement and suggests the acquirement of American civilization.

Finally, we physicians must realize that on us lies the burden of inaugurating this campaign and should institute a beginning as soon as possible. What more influential body of men is there in this country to-day than the American Medical Association? Why should we not make the greatest effort in this direction and be recognized as the leaders in the fight?

Taylor Building.

ABSTRACT OF DISCUSSION

DR. S. W. KELLEY, Cleveland, Ohio: Dr. Royster spoke of the short time for pediatrics in the college course, and of its being doubled up with some other branch of teaching in many colleges, being taught by the teacher of obstetrics or gynecology or toxicology or what not. These conditions, among others, have been taken up for consideration by the Association of American Teachers of the Diseases of Children and, after some studies of the subject two years ago a report was adopted at the session held in Atlantic City in June, 1909. This report declared, among other things, that "every medical college should have a chair of pediatrics. It should be a full professorship, quite independent; i. e., not subordinate to any other chair." The association declared also in favor of devoting as much time to pediatrics as to any other practical branch; that 10 per cent. of the third and fourth years, or not less than 190 hours, should be the minimum.

The Council on Medical Education of the American Medical Association has also taken some action recommending an increased allowance of time to 180 hours.

In the Association of American Medical Colleges, the Committee on Curriculum for the Clinical Years, at the meeting at Baltimore last March, advanced the time devoted to pediatrics from 100 hours to 150 hours. This has not yet gone into effect, but the report will be acted on next year and whatever is adopted will not merely be recommended but will become the law of the association as the minimum requirement. This time allowance, of course, does not come up to the ideal, but is certainly a very encouraging advance.

THE JOURNAL A. M. A. gives an account of the meeting of the College Association in brief abstract; it may interest you to hear that the report goes on to say that "the allowance for pediatrics is intended to include instruction in the exanthemata. In many other ways medicine and pediatrics overlap. Useless repetition can only be avoided by a proper understanding between the teachers of these two subjects, and a certain elasticity should be allowed a school for the purpose of assigning time to one subject or the other according to where the borderland subjects can best be taught. In the same way pediatrics and surgery touch and overlap. In one subject or the other the surgery peculiar to children should receive attention. Valuable suggestions in relation to the teaching of pediatrics will be given in an appendix to this report."

PUBLIC HEALTH ORGANIZATION IN NEBRASKA*

D. T. QUIGLEY, M.D.,
NORTH PLATTE, NEB.

The purpose of this paper is to report the organization of the public health officers of the State of Nebraska, to give the plan of the organization and to recommend the plan to other states where such a movement has not yet been made, rather than to recount the work already accomplished.

On June 8, 1909, in response to a call sent out, a large number of the city and county physicians of the state met in Omaha and organized what is now the Nebraska State Health Association. For several weeks before the meeting, and before the call was sent out, interest was aroused by the following letter, which was published in newspapers throughout the state:

HEALTH OFFICERS SHOULD ORGANIZE

North Platte, Neb.

To the Editor:—In line with the present rapidly developing sentiment in favor of the idea of preventing disease instead of attacking it after it has developed, and the spread of life-saving medical intelligence, I want to bring before the public the necessity of organization of the public health officers and the need of public support of such an organization after it has been effected. Much good would result if the public health officers of the state were organized and would hold regular meetings, where the ways and means for preserving public health might be discussed, improvements and advances noted, and the force of the organized body brought to bear on the enforcement of such regulation as might be necessary. City and county health officers have been inclined to be passive and very little work of an active and aggressive nature has been done; but, in view of the fact that an enormous amount of the diseases that now afflicts the people of our state could be absolutely prevented, it seems reasonable to suppose that one of the first steps to secure more nearly ideal health conditions would be perfection of such an organization as I have cited.

D. T. QUIGLEY, City Physician.

This was followed up by a letter to every city and county physician in the state as follows:

CALL FOR STATE MEETING OF THE PUBLIC HEALTH OFFICERS OF NEBRASKA

To all city and county physicians and other public health officers of the state of Nebraska:

Dear Doctor:—This circular letter is sent to every public health officer in the state for the purpose of effecting a state organization. The need of such an organization is apparent

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

when we realize that there is much to be gained in enforcing health regulations, if the city or county physician is backed up by a compact and well organized state association. This, however, is of minor importance compared with the benefits that will come to each community and the state by the wide dissemination of knowledge on preventive medicine that will result. The dominant note in all medicine to-day is prevention. There is much that is new in this field. Most of us can teach others something; we can all learn, and we shall all be better physicians and better health officers, if we get together and mix our experience and our learning. Nebraska, as a state, ranks first in the intelligence of her people; let us see that she ranks first in the intelligence of public health officers by making a good, strong association that will be a pattern for other states and do untold good by furthering the work of protecting our people from disease and death. We want to have this meeting as early as possible so as to get after the hot weather diseases, flies, etc., and that we may report what has been done at the Section on Hygiene of the American Medical Association at the Atlantic City meeting, June 8. The date set for this meeting, therefore, is June 7 and 8; the place, the Rome Hotel, Omaha. Return the enclosed postal, at once, stating whether or not you will be present. Get in as a charter member if possible. Charge your expense for the trip to your city or county. Very few will refuse to pay, if the benefit to the community from your presence at the meeting is explained to them.

DR. D. T. QUIGLEY, North Platte, Neb.

At this first meeting the subjects of tuberculosis, medical inspection of schools and the carrying of disease by insects, flies, etc., were taken up and fully discussed. As all the leading papers in the state had reporters at the meeting, the intelligence in regard to these diseases that was spread broadcast throughout the state amounted to a great deal, and health officers, even in districts not represented at the meeting, found it easier to enforce their regulations in regard to preventive measures. At the second meeting, which was held in Lincoln, a large number of persons who were not public health officers having become interested, the by-laws were so amended as to take in all interested outsiders as associated members, the only restriction being that they were not allowed to vote on any question involving the enforcement of any health regulations or rules. These associate members are very valuable in keeping up interest in health matters in their respective localities, and, in an association in which the active members hold office by political appointment usually only for one year, it seemed wise to make such a provision, if only to take care of the older members. The new health officer, coming in, is usually enthusiastic enough to seek membership, while the old one, going out, has learned to love the work well enough so that he will stay and give his colleagues the benefit of his experience. It will be seen that the possibilities for the growth of such an association are great.

The plan of the association is to spread knowledge of the prevention of disease in every way possible—by newspapers, lectures, etc. We expect to have a lecturer on public health at every *chautauqua* in the state this summer. The plan also includes the use of the influence of the association toward the passage of laws directed to the betterment of the public health, such as providing for a state lecturer on tuberculosis and venereal disease, the prevention of the marriage of the diseased, the idiotic and the insane, the prevention of the spread of disease by railroads, providing for medical inspection of schools, providing for quarterly bulletins to be issued by the state board of health and sent to every tax-payer in the state giving seasonable information on the prevention of disease, etc.

It will be seen that there is much to be done, and much can be done by an association like this in every state. I addressed the governors' conservation congress in March on the need for this kind of legislation and was very glad to see that the conservation of human life stirred up more interest than any other topic taken up by the assembly. All the recommendations made were incorporated into the resolutions adopted by the meeting. An association of this kind in every state giving its endorsement to such measures as Senator Owen's bill would help much toward the passage of favorable medical legislation.

THE PERMANENT ELIMINATION OF YELLOW FEVER*

J. H. WHITE, M.D.
NEW ORLEANS

Where the means for combating any disease is made known, it is little less than criminal to let such agencies fall into disuse. The American Commission in Cuba placed the necessary knowledge directly at our disposal in 1900, and we have evolved the correct practice since that time to such extent that we no longer fear epidemic yellow fever, but there still remains a goodly share of the work to be done. Most of us have vaguely considered the question of total eradication—I among the rest—but no practical solution of all points presented itself to me until I recently had a talk with the one man who probably knows more of yellow fever than any other, and his remarks put me on the track of the final solution—to Dr. Carter, of our service, therefore, belongs entirely the credit for most that I shall say.

We find this disease in endemic and epidemic foci. Endemicity, to be maintained, demands:

(a) A sufficient birth rate to furnish a very steady, continuous supply of non-immunes (babies), and therefore demands for its habitat a city of considerable size, unless conditions are peculiar, as below.

(b) The supply of non-immunes may be existent in a smaller place through the presence of a constant influx of non-immunes from the back country. This is exactly the reverse of what has many times been stated, viz: that the Hinterland infected the coast town. This latter erroneous impression I think Carter was the first to contravene.

Now, if we accept these two as the necessary corollaries for endemicity, it is readily seen that once endemicity is destroyed, we can also destroy *pari passu* all chance of epidemic occurrence. It has been fully demonstrated at Habana, Santiago, Cienfuegos, Vera Cruz, Rio Janeiro, Colon, and Panama that epidemic centers can be eliminated.

We know that the remaining foci are Cartagena, Sabanilla, Baranquilla, Bahia, Manaus, Para, Pernambuco, Santos, Guayaquil, and possibly the capitals of British, Dutch, and French Guiana on the American continent, and one or two points at most on the Gulf of Guinea, in Africa.

The total population of all these places will not exceed 1,500,000, and I am fully justified in saying that 5 mills per diem per capita would cover the cost, even at American prices, of holding these places in sanitary control—which control continued for a space of three

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

years, at a total outlay of about \$10,000,000, would mean that yellow fever, which has been the scourge of commerce for 400 years, would be no more, and maritime quarantine, save for plague alone, would become an unpleasant memory.

Such work would require cooperation with us on the part of the Latin-American countries and Great Britain, and, if Cayenne and Parimaribo are foci, of France and Holland; but I do not doubt the feasibility of obtaining all necessary cooperation, save for one of the Latin countries, since all but that one are on the best of terms with us, and even that one might be persuaded, in time.

The whole program could be summed up briefly as follows:

(a) Each center under one man's control, and he given full power to make a steady, insistent, and minutely exact fight on all *Stegomyia* breeding places.

(b) No attempt made to handle the sick, and so rouse the ire of the individuals.

(c) Be most careful to make it plain that subordinates shall annoy no one, and then see that they do not annoy.

The officer should approach the question of human carriers of the disease, if at all, solely through friendly suggestion to local authority, after getting on intimate terms, and then only to discreet officials, for fear of arousing opposition to his own particular work, which, in the end, would be absolutely sure of success. Could this be done, the medical profession would have to its credit an achievement that would be worth in money to the western world each year all of its cost, and to humanity more than can be estimated.

I wish to reiterate that I claim no originality in the foregoing, it being simply deductions from the splendid work of Colonel Gorgas, observations during my own work and, as before stated, Carter's suggestion. The idea of presenting such a conclusion having grown out of a statement made by Colonel Kean at the Atlantic City session in 1909, that we should wipe out yellow fever in ten years.

EXPERIMENTAL POLIOMYELITIS IN MONKEYS

EIGHTH NOTE: FURTHER CONTRIBUTIONS TO THE SUBJECTS OF IMMUNIZATION AND SERUM THERAPY*

SIMON FLEXNER, M.D.

AND

PAUL A. LEWIS, M.D.

NEW YORK

In our seventh note¹ on experimental poliomyelitis we treated of some of the phenomena of active immunization and passive serum protection in respect to epidemic poliomyelitis, and in this connection we wish to record some additional observations of the same general import. It can now be accepted as established that human beings and monkeys who have passed through an attack of poliomyelitis have come to contain in their blood certain neutralizing principles for the virus of poliomyelitis; that these principles are readily demonstrable by animal tests for two or more years in human

beings, and that they probably persist for as great a period in monkeys. It has, moreover, been shown that monkeys which have recovered from an attack of poliomyelitis are highly refractory to reinoculation with the virus of poliomyelitis, and it is probable that the recovered human beings are similarly protected from reinfection. In both instances the attack has conferred a strong active immunity. But to have had and to have recovered from poliomyelitis is not the sole way in which an active immunity can be achieved, since it has been proved possible to immune monkeys actively by injecting into the subcutaneous tissue either the virus of full strength or one modified by chemical agents (for instance, glycerin).

ARTIFICIAL ACTIVE IMMUNIZATION

This mode of producing active immunity has not up to the present time been developed into a uniformly successful and safe method, since of the treated animals some do not develop a strong immunity and others develop paralysis as a result of the treatment.

The test of this active immunity thus far published consisted of the ability to resist a large intracerebral injection of the filtrate that in far smaller quantities produces paralysis in the control animals. The active immunity has been secured either from a single large subcutaneous injection of the crude or modified virus as represented by emulsions of the spinal cord taken from recently paralyzed monkeys, or by repeated injections of gradually increased amounts of the crude virus.

SERUM NEUTRALIZATION OF THE VIRUS

It has been shown that the blood-serum of human beings and monkeys that have recovered from an attack of poliomyelitis contains neutralizing principles for the virus of the disease, which principles are absent from normal serum. Moreover, it is safe to assume that these neutralizing substances are the indication and cause of the active immunity which is responsible for the refractory state of the animals to reinfection. Hence there should exist in the serum of the directly actively immunized animals, which have not been made to pass through an attack of poliomyelitis, similar neutralizing principles. When an active filtrate containing virus is mixed with the serum of actively immunized monkeys and incubated for a period at 37 C. it no longer sets up paralysis on being injected into the brain of normal monkeys.

In the previous neutralization experiments with monkey serum reported, the serum had been taken from animals in which, after recovery, reinforcement of the immunity had been attempted either purposely by subsequent injections of considerable quantities of active virus or had been circumstantially produced in the course of tests made to determine the existence of immunity to reinfection. We have since ascertained that without reinforcement the serum of monkeys that have recovered from the paralysis contains readily appreciable quantities of this principle. This experiment has established the fact that monkeys react precisely as human beings do in respect to the disease, since their serum as such after recovery possesses marked neutralizing power for the virus *in vitro*; and it indicates that the test would probably disclose the fact of an atypical attack of poliomyelitis such as is embraced in the so-called abortive type of the affection.²

* From the Laboratories of the Rockefeller Institute for Medical Research.

1. The previous articles have appeared in THE JOURNAL A. M. A., Nov. 13, 1909, p. 639; Dec. 1, 1909, p. 1913; Dec. 18, 1909, p. 2095; Jan. 1, 1910, p. 45; April 2, 1910, p. 1140; May 28, 1910, p. 1780; and Jour. Exper. Med., xii, 227.

2. Netter and Levaditi have indeed determined that the blood of a patient who had suffered an abortive attack of poliomyelitis contained the neutralizing principle.

EXPERIMENTAL SERUM THERAPY WITH MONKEY SERUM

In the seventh note we pointed out that the serum derived from immune monkeys that had passed through an attack of poliomyelitis possessed therapeutic properties for the experimental disease. It was stated that if the quantity of virus injected into the brain was not in excess of a given dose the development of paralysis could, in some cases, be prevented by making several injections of the serum, by lumbar puncture, into the subarachnoid space, and that infection by way of the nasal mucosa could also and with greater certainty be prevented by the serum injections. We have also ascertained that the serum of directly immunized monkeys possesses similar therapeutic properties.

EXPERIMENTAL SERUM THERAPY WITH HUMAN SERUM

That human serum derived from children who have passed through an attack of poliomyelitis possesses neutralizing power for the virus of poliomyelitis has been stated already; it can now be stated that it possesses therapeutic value also. When the subarachnoid injections are begun twenty-four hours after the intracerebral inoculation of the virus, the development of paralysis can be entirely prevented in a certain number of the animals, while in another number the onset of paralysis is much delayed.

The period of incubation in the control animals ranged from seven to eleven days and in some of the treated animals that finally became paralyzed it was as great as twenty-six and twenty-seven days. The serum injection begun twenty-four hours after the inoculation, was carried out on three successive days, after which an interval of three days was allowed to pass, when three more daily injections were given. It seems probable that had the injections been resumed after another interval of rest the last vestige of the virus in the tissues would have been destroyed.

NEUTRALIZED VIRUS PRODUCES NO IMMUNITY

We have seen that actively immunized monkeys, the result of obvious disease and paralysis, or the product of gradual or abrupt accommodation to the virus, not only yield a serum that contains neutralizing properties for the virus, but are themselves highly refractory to reinfection with a highly potent virus. The fact has been repeatedly observed that failure to develop paralysis after an intracerebral inoculation of an active virus does not lead to any increase in resistance of the monkeys to subsequent infection by the same route. The animals which have once withstood an inoculation respond on another occasion as readily as the control animals. No explanation for this discrepancy has been found.

It is of interest, therefore, to learn that monkeys which have been protected from paralysis through the employment of mixtures of virus and immune serums, or as result of treatment by subarachnoid injections of immune serums, do not exhibit any unusual degree of resistance to subsequent intracerebral injections of active virus made at periods of several weeks to four or five months after the condition of the original experiments. Three important points are developed by this fact: that neutralized mixtures of virus and immune serum do not lead to any degree of active immunization; that the therapeutic action of the serum is associated with restraint of multiplication of the virus such as would be required to establish any grade of active immunity; and

that a simple passive immunity is either not produced by the serum injections, or is of brief duration or small amount.

ARTIFICIAL IMMUNE SERUM

We have continued our efforts to produce an immune serum in some of the lower animals that might possibly become the source of a therapeutic serum. This work is being actively pursued at present, but we wish to report on an indication in the direction of our search. It has been found that normal sheep serum possesses a definite although slight neutralizing power for the filtered virus, and that the injection of emulsions of the spinal cord and brain of recently paralyzed monkeys into the sheep augments this property of neutralization.

The serum treatment of poliomyelitis is at present in the experimental state, and how soon, or whether ever at all, it will be applicable to the spontaneous disease in human beings cannot be predicted.

Sixty-sixth Street and Avenue A.

NOTES ON THE TECHNIC OF TRANSFUSION
OF BLOOD

J. SHELTON HORSLEY, M.D.

Professor of Principles of Surgery and Clinical Surgery in the
Medical College of Virginia; Surgeon to Memorial Hospital

RICHMOND, VA.

Transfusion of blood has been brought into prominence in the last few years as an emergency life-saving measure. This operation has been developed by Carrel, Guthrie, Crile and others to such a point as to render its performance quite satisfactory in the hands of an average surgeon who has done enough experimental work on the lower animals to perfect his operative technic. Its advantages have been so well demonstrated by clinical use that its position among surgical procedures is assured. In two kinds of cases it is particularly appropriate. The class of cases exsanguinated to such an extent that even when the volume of blood is increased by salt solution life cannot be maintained, can be saved only by transfusion of blood. The other group consists of patients who have been so enfeebled by disease that they cannot stand the operation necessary to cure them. Here transfusion of blood increases the resistance of the patient and often enables him safely to undergo surgical procedures that otherwise would probably be fatal. The field may yet be widened, but the above two classes of cases already constitute a sufficiently broad field to render the operation one that should be frequently performed.

The similarity between the development of arterial suture and the evolution of intestinal suture is very striking. When intestinal surgery began to come to the front there was a host of mechanical devices, of which the Murphy button was the most prominent. As experience increased it was seen that, other things being equal, the simpler an apparatus was the more desirable it would be. Gradually it was found that everything that could be accomplished by a mechanical contrivance could be equally well done with a needle and thread. Consequently mechanical contrivances are now rarely used in intestinal surgery. In arterial suture, as in the transfusion of blood, there is likewise a host of devices, of which the cannula of Crile is the most prominent. After the technic of arterial suture develops the various rings, forceps and cannulas will probably be discarded, as was the case in intestinal surgery, and the needle and thread will be adopted. Arterial suture requires experimental

the eczema entirely disappeared. The medicaments and lotions tried to relieve this itching of the vulva were oils (bland and medicated), powders, ointments, witch hazel, phenol, zinc, lead, bicarbonate of soda solutions, menthol preparations, etc.

It is almost fair to assume that this woman, who is perfectly comfortable on the present diet and suffering no symptoms from the diabetes, will not die, under this management, from this disease. The story of this patient shows what can be done to make a patient with glycosuria not only comfortable but all but well.

New and Nonofficial Remedies

SINCE THE PUBLICATION OF THE BOOK "NEW AND NONOFFICIAL REMEDIES, 1910," THE FOLLOWING ARTICLES HAVE BEEN ACCEPTED BY THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION. THEIR ACCEPTANCE HAS BEEN BASED LARGELY ON EVIDENCE SUPPLIED BY THE MANUFACTURER OR HIS AGENT AND IN PART ON INVESTIGATION MADE BY OR UNDER THE DIRECTION OF THE COUNCIL. CRITICISMS AND CORRECTIONS TO AID IN THE REVISION OF THE MATTER BEFORE PUBLICATION IN THE BOOK ARE ASKED FOR.

THE COUNCIL DESIRES PHYSICIANS TO UNDERSTAND THAT THE ACCEPTANCE OF AN ARTICLE DOES NOT NECESSARILY MEAN A RECOMMENDATION, BUT THAT SO FAR AS KNOWN IT COMPLIES WITH THE RULES ADOPTED BY THE COUNCIL.

W. A. PUCKNER, SECRETARY.

(Continued from page 503)

DIASPIRIN.—Diaspirin is succinyl disalicylic acid, $\text{CO}(\text{O.C}_6\text{H}_4\text{COOH})\text{.CH}_2\text{.CH}_2\text{.CO}(\text{O.C}_6\text{H}_4\text{COOH})$.

Diaspirin is a salicylic acid derivative, produced by the interaction of the two carboxyl groups of succinic acid with the phenolic hydroxyls of two molecules of salicylic acid, with the elimination of 2 molecules of water, thus: $\text{COOH.CH}_2\text{.CH}_2\text{.COOH} + 2\text{HO.C}_6\text{H}_4\text{COOH} = \text{CO}(\text{O.C}_6\text{H}_4\text{COOH})\text{.CH}_2\text{.CH}_2\text{.CO}(\text{O.C}_6\text{H}_4\text{COOH}) + 2\text{H}_2\text{O}$.

It is prepared by the action of succinyl dichloride upon salicylic acid.

Diaspirin is an odorless and almost tasteless white crystalline powder, said to melt at about 178°C . (352.4°F .) (Specimens examined by the Council were found to melt at 168°C . Corr.) Soluble with difficulty in cold alcohol and glacial acetic acid; scarcely soluble in water. By heating with caustic alkalis it decomposes into succinate and salicylate. Diaspirin is a dibasic acid which reacts with bases, organic or inorganic, to form salts.

Diaspirin produces the effects of salicylates. The following special claims are made for it: That it passes unchanged through the stomach, producing no irritation, but is split into its constituents in the intestine; that it exerts a strong diaphoretic effect.

Actions and Uses.—The same as those for salicylic acid.

Dosage.—1 Gm. (15 grains) three or four times daily.

Manufactured by the Farbenfabriken vorm. Friedr. Bayer & Co., Elberfeld, Germany. (Farbenfabriken, of Elberfeld Co., New York). U. S. patent No. 874, 929. U. S. trademark applied for.

FERRATIN—Sodii Ferrialbuminas.—Sodium Ferrialbuminate.—Ferratin is the sodium salt of ferrialbuminic acid, containing iron in the ferric state in organic combination, equivalent to 6 per cent. metallic iron.

Sodium ferrialbuminate occurs naturally in the organs of mammals, especially in the liver. Ferratin is prepared from egg albumin and chemically pure iron salts in the presence of alkalis.

Ferratin is a light brown, tasteless powder, having a faint odor. It is soluble in weak alkaline aqueous solutions, from which solutions it is precipitated by hydrochloric acid. On dissolving 0.3 Gm. ferratin in 10 Cc. of water with the aid of a few drops of ammonia water, and then adding an equal volume of a 25 per cent. potassium carbonate solution, no precipitation occurs.

Actions and Uses.—See Organic Iron Compounds.

Dosage.—0.5 Gm. ($7\frac{1}{2}$ grains) three to four times daily.

Manufactured by C. F. Boehringer & Soehne, Waldhof, Mannheim, Germany. (Merck & Co., New York). U. S. patent No. 505986. U. S. trademark No. 24,228.

ARSENOFERRATIN—Sodii Arsenoferrialbuminas.—Sodium Arsenoferrialbuminate.—Arsenoferratin is an arsenic iron albumin compound, obtained by introducing the element arsenic into the molecule of ferrialbuminic acid. Arsenoferratin contains iron in the ferric state, in organic combination equivalent to 6 per cent. metallic iron and arsenic, equivalent to 0.06 per cent. elementary arsenic.

Arsenoferratin is a brown, almost odorless and tasteless powder. It is soluble in water and easily soluble in dilute alkaline solutions.

Actions and Uses.—Arsenoferratin has the pharmacologic action of organic compounds of iron and of arsenic.

Dosage.—0.5 Gm. ($7\frac{1}{2}$ grains) three to four times daily.

Manufactured by C. F. Boehringer & Soehne, Waldhof, Mannheim, Germany. (Merck & Co., New York). U. S. trademark No. 24,228.

Arsenoferratin Tablets.—Each tablet contains arsenoferratin 0.25 Gm. (4 grains).

Arsenoferratin Liquor.—Liquor Ferratini Arsenati.—Arsenoferratin is a 5 per cent. solution of arsenoferratin.

Arsenoferratin, 5 parts, is dissolved with the aid of a small quantity of sodium hydroxide in water, 63 parts, glycerin, 20 parts, alcohol, 6 parts, and Angostura essence, 1 part.

Dosage.—4 to 8 Cc. (1 to 2 fluidrams) three to four times daily.

For the determination of Iron and Arsenic in Arsenoferratin, the following methods are furnished:

Twenty-five Cc. of arsenoferratin are evaporated to a viscid consistency in a capacious tared crucible and the residue heated in a drying oven at 100°C . for three hours to constant weight. After the crucible and its contents have been allowed to cool in a desiccator, it is weighed. The weight of the evaporated residue multiplied by 4 should be about 23. The weighed residue is now carefully incinerated, and finally ignited. After it has cooled, it is moistened with nitric acid, and again ignited, and finally taken up with 10 Cc. hydrochloric acid. The solution is diluted with 30 Cc. water, and when cold, 3 Gm. potassium iodide are added and the mixture allowed to stand for an hour in a well-stoppered bottle at the ordinary temperature. It is then titrated with decinormal sodium thiosulphate solution. The iodine liberated should require about 12.5 Cc. of tenth normal thiosulphate solution.

Fifty Cc. of the arsenoferratin contained in a distillation flask of about 500 Cc. capacity, are heated on a water bath and evaporated to about one-third of its original volume. To the residue are now added 80 Cc. of arsenic-free concentrated hydrochloric acid and 20 Cc. arsenic-free, 25 per cent. solution of ferrous chloride, and the arsenic chloride distilled over, the receiver being kept well cooled by means of cold water. The contents of the receiver are then supersaturated with sodium bicarbonate, and the arsenic then titrated with the tenth-normal iodine solution; 0.4 Cc. decinormal iodine solution should be required, corresponding to a content of 0.003 Gm. in 100 Cc. arsenoferratin.

THIGENOL.—Solution of Sodium Sulpho Oleate, Roche.—Thigenol is a solution of the sodium salts of synthetic sulpho-oleic acids, containing 2.85 per cent. sulphur.

Precipitated sulphur is dissolved by boiling in the glyceride of oleic acid; the resulting solution is treated with sulphuric acid, during which process sulphurous acid escapes, and a sulpho-oleic acid is separated out. The separated sulpho-acid is then obtained by pouring into water, and subsequently washing thoroughly. By treatment with solution of sodium hydroxide, there results a solution of sodium sulpho-oleate, which is evaporated in vacuo until it has a specific gravity of 1.05 to 1.00.

Thigenol is a dark brown liquid, having a faint sulphurous odor. It is soluble in one or more parts of water, dilute alcohol, glycerin, chloroform, oily or fatty bases, with any one of which it mixes freely. When water is the vehicle employed, it should be distilled; hard water will cause a precipitate. Thigenol is incompatible with mineral acids or acetic acid.

Actions and Uses.—Thigenol is said to have the actions of sulphur. It is claimed to stimulate granulation, restrict secretions and to be antipruritic.

It is used in diseases of the uterus and its appendages and in skin diseases in which sulphur is commonly employed.

Dosage.—0.2 to 0.6 Gm. (3 to 10 grains) in plain or sweetened water. Thigenol is used locally either in the pure state or mixed in any desired proportion with ointment bases, fats or glycerin according to the intensity of action required.

Manufactured by F. Hoffmann-LaRoche & Co., Basel, Switzerland. (The Hoffmann-LaRoche Chemical Works, New York). U. S. trademark No. 42,295. Not patented.

SUPRACAPSULIN.—The name used for epinephrine by The Cudahy Packing Co., South Omaha, Neb.

Not patented. U. S. trademark No. 72,580.

Supracapsulin Solution.—A solution 1:1000 of supracapsulin in normal salt solution with small quantity of sulphite and 0.5 per cent. of chloral.

(To be Continued)

MEDICAL COLLEGES OF THE UNITED STATES

Data Prepared by the Council on Medical Education

Below are given brief descriptions of the medical colleges in the United States and Canada that are legally chartered to teach medicine, several of which do not grant degrees. The name, address, year of organization, history and date when first class graduated is given in each instance. Unless otherwise stated, a class graduated each subsequent year. Where official reports have been received from the college, information regarding faculty, entrance requirements, length of term, fees, students (excluding specials and postgraduates), graduates, name of dean and next session is given without discrimination, regardless as to whether the college is sectarian or not. In a few instances where such reports were not received the information published is from other reliable sources. Extracts of rules and the membership of the Association of American Medical Colleges is shown following the list of colleges. Figures showing population of cities and states are taken from the United States Census Bureau's estimates for 1909.

ALABAMA

Alabama, population 2,112,465, has two medical colleges, the Medical Department of the University of Alabama and the Birmingham Medical College, located, respectively, in Mobile and Birmingham. The population of Mobile is 45,122 and of Birmingham, 49,533.

Birmingham

BIRMINGHAM MEDICAL COLLEGE, Avenue F and Twentieth Street. —Chartered in 1894. The first class graduated in 1895. There are 22 professors and 12 assistants, total 34. The course of instruction embraces four separate sessions of eight months each. The fees are \$100 for each of the first three years and \$125 for the fourth. The Dean is Dr. B. L. Wyman. Registration, 1909-10, 209; graduates, 23. The seventeenth session begins Sept. 28, 1910, and ends May 26, 1911.

Mobile

UNIVERSITY OF ALABAMA SCHOOL OF MEDICINE, St. Anthony and Lawrence Streets. —Organized in 1859 as the Medical College of Alabama. Classes were graduated in 1861 and in all subsequent years except 1862 to 1868, inclusive. It was reorganized as the Medical Department of the University of Alabama in 1897. All property was transferred to the University of Alabama in 1907. Present title assumed in 1909. The faculty consists of 8 professors and 17 lecturers and assistants, a total of 25. The course of study covers four years of seven months each. The total fees for each of the first three years is \$100; for the fourth year, \$125. The Dean is Dr. Rhett Goode. The total registration for 1909-10 was 179; graduates, 40. The forty-fifth session begins Sept. 19, 1910, and ends May 9, 1911.

ARKANSAS

Arkansas, population 1,476,582, has two medical colleges, the Medical Department of the University of Arkansas and the College of Physicians and Surgeons, both located in Little Rock, a city of 43,688.

UNIVERSITY OF ARKANSAS MEDICAL DEPARTMENT, Second and Sherman Streets. —Organized in 1879 as the Medical Department of Arkansas Industrial University. The first class graduated in 1880. It assumed the present title in 1899. The faculty consists of 22 professors and 16 lecturers and assistants, total, 38. The course of study covers four years of eight months each. The fees are \$100 for each of the first three years and \$125 for the fourth year. The secretary is Dr. C. E. Witt. Total registration, 1909-10, was 171; graduates, 26. The thirty-second session begins Sept. 15, 1910, and ends May 6, 1911.

COLLEGE OF PHYSICIANS AND SURGEONS, Lincoln Avenue, north of the Union Station. —It was organized in 1906. The first class graduated in 1907. The faculty consists of 28 professors and 12 lecturers and assistants, a total of 40. The course of study covers four years of seven months each. The fees are \$100 for each of the first three years and \$125 for the fourth year. The Dean is Dr. J. P. Runyan. The total registration for 1909-10 was 104; graduates, 29. The fifth session begins Oct. 1, 1910, and ends May 1, 1911.

CALIFORNIA

California, population 1,729,543, has eight medical colleges. Four are located in San Francisco, a city of 400,000 inhabitants. They are Leland Stanford Junior University College of Medicine, Medical Department of the University of California, Hahnemann Medical College of the Pacific and the College of Physicians and Surgeons. The College of Physicians and Surgeons and the California Eclectic Medical College and the Los Angeles Clinical Department of the University of California are situated in Los Angeles, population 300,000. The Oakland College of Medicine and Surgery is in Oakland, population 225,000. The College of Medical Evangelists is located at Loma Linda, a village near San Bernardino, this latter place having a population of 13,500.

Loma Linda

COLLEGE OF MEDICAL EVANGELISTS. —Organized in 1900. The faculty numbers 10. The course extends over five years of nine months each, but includes a study of the Bible, pastoral training and other non-medical subjects. The total fees each year are \$100; matriculation fee, \$5, payable but once; graduation fee, \$10. The Dean is Dr. George Knapp Abbott. The total registration for 1909-10 was 10; no graduates. The second session begins Sept. 29, 1910, and ends June 27, 1911.

Los Angeles

COLLEGE OF PHYSICIANS AND SURGEONS, MEDICAL DEPARTMENT, UNIVERSITY OF SOUTHERN CALIFORNIA, 516 East Washington Street. —Organized in 1903, first class graduated in 1905, became Medical Department, University of Southern California August 11, 1909. The course covers four years of nine months each. The faculty consists of 12 professors and 32 associate professors, lecturers and instructors, a total of 44. The fees are \$150 per year, not including matriculation fee, paid but once, \$5, and graduation fee, \$25. The Dean is Dr. Charles W. Bryson, Delta Building, Los Angeles. The registration for 1909-10 was 69; graduates, 12. The next session begins Sept. 14, 1910 and ends June 15, 1911.

CALIFORNIA ECLECTIC MEDICAL COLLEGE, 846 Lyon Street. —Organized in 1879 at Oakland as the California Medical College. Removed to San Francisco in 1887. Suspended in 1906. Reorganized at Los Angeles with the present title in 1907. Classes were graduated in 1880, and in all subsequent years except 1907. It has a faculty of 30 professors. The Dean is Dr. J. A. Munk. The registration for 1909-10 was 22; graduates 2. The 32d session begins Sept. 19, 1910, and ends May 18, 1911.

Oakland

OAKLAND COLLEGE OF MEDICINE AND SURGERY, Thirty-first and Grove Streets. —Organized in 1900, opened in 1902. The first class graduated in 1906. The faculty numbers 33. The course covers four years of nine months each, and the classes are limited to ten students each. The total fees for each of the four years respectively are \$210, \$200, \$150 and \$150. The Registrar is Dr. Edward N. Ewer. The total registration for 1909-10 was 20; graduates, 3. The ninth session begins Aug. 15, 1910, and ends May 20, 1911.

San Francisco

HAHNEMANN MEDICAL COLLEGE OF THE PACIFIC, Homeopathic, Sacramento. —Organized in 1881 as the Hahnemann Medical College, located in 1884. In 1888 it became the Hahnemann Medical College of San Francisco. It assumed the present name in 1902. It has a faculty of 26 professors and 16 lecturers, instructors, etc., a total of 42. The course covers four years of seven months each. Total fees for the first year are \$155, and \$100 for each of the other three. The Dean is Dr. James W. Ward, 1380 Sutter Street. The total registration for 1909-10 was 34; graduates, 1. The 29th session begins Aug. 11, 1910, and ends April 27, 1911.

COLLEGE OF PHYSICIANS AND SURGEONS, 344 Fourteenth Street. —Organized in 1896. The first class graduated in 1897. The faculty numbers 60. The course covers four years of nine months each. The fees are \$150 each year. The Dean is Dr. Ethan H. Smith. Registration for 1909-10 was 29; graduates, 7. The fifteenth session begins Sept. 1, 1910, and ends June 1, 1911.

San Francisco-Palo Alto

LELAND STANFORD JUNIOR UNIVERSITY, DEPARTMENT OF MEDICINE, University Campus, Palo Alto, and Sacramento and Webster Streets, San Francisco. —Organized in 1871 as the Department of the University of the Pacific. Received in 1870. It became the Medical Department of the University College in 1873. Became Cooper Medical College in 1882. A class was graduated in 1890 and in each subsequent year except 1865 to 1869, inclusive. In 1908 an agreement was made to unite with the Leland Stanford Junior University. By the terms of this agreement Cooper Medical College would continue to teach until the classes which entered prior to August, 1909, had been graduated. The last class will be graduated in 1912. Three years of collegiate work are required for admission. During the next session the work of the first and second years will be given at Palo Alto and the third and fourth years at San Francisco. The faculty of the combined schools consists of 39 professors and 35 lecturers, assistants, etc., a total of 74. The course covers four years of nine months each. The total fees for each of the first and second years are \$175; for the third

year, \$170, and for the fourth year, \$185. The Secretary of the faculty is Dr. Emmet Rixford, San Francisco. The total registration for 1909-10 was 95; graduates, 17. The next session at Palo Alto begins Aug. 25, 1910, and ends May 22, 1911. At San Francisco, the next session begins Aug. 15, 1910, and ends May 5, 1911.

San Francisco-Berkeley-Los Angeles

UNIVERSITY OF CALIFORNIA MEDICAL DEPARTMENT. University Campus, Berkeley; Second and Parnassus Avenues, San Francisco and Buena Vista and Alpine Streets, Los Angeles.—Organized in 1863 as the Toland Medical College. The first class graduated in 1865. In 1872 it became the Medical Department of the University of California. In 1900 it absorbed the College of Medicine of the University of Southern California, which became a clinical department at Los Angeles. Two years of collegiate work are required for admission. The work of the first two years is given at Berkeley and the work of the last two years at either Los Angeles or San Francisco. The faculty is composed of 33 professors and 84 associates and assistants, a total of 117. The course covers four years of nine months each. The fees are: Matriculation, \$5; tuition, \$150 each year. The Dean at San Francisco is Dr. Arnold A. D'Ancona; at Los Angeles, Dr. W. Jarvis Barlow. Total registration of the two schools for 1909-10 was 107; graduates, 13. The 38th session at San Francisco begins Aug. 22, 1910, and ends May 17, 1911. The next session at Los Angeles begins Sept. 15, 1910, and ends May 31, 1911.

COLORADO

Colorado, with a population of 653,000, has two medical colleges. The Denver and Gross College of Medicine is in Denver, which has a population of 156,726, and the Colorado School of Medicine is at Boulder, population 12,000. These two schools will be merged Jan. 1, 1911, in case the amendment to the state constitution is secured giving the State University the right to teach medicine in Denver.

Boulder

UNIVERSITY OF COLORADO SCHOOL OF MEDICINE.—Organized in 1883. Classes were graduated in 1885 and in all subsequent years, except 1898 and 1899. The faculty embraces 23 professors and 20 lecturers and assistants, a total of 43. The work embraces a graded course of four years of nine months each. The entrance requirements are two years of college work counting toward a degree in arts in an accredited college or university. The tuition is \$75 per year; there are no other fees. The Dean is Dr. William P. Harlow. The total registration for 1909-10 was 77; graduates, 8. The twenty-ninth session begins Sept. 12, 1910, and ends June 7, 1911.

Denver

THE DENVER AND GROSS COLLEGE OF MEDICINE, 1025 Fourteenth Street.—It is the Medical Department of the University of Denver. Organized in 1902 by the union of the Gross Medical College (organized in 1887) with the Denver College of Medicine (organized in 1880). Classes were graduated in 1903 and in all subsequent years. This college will be merged into the University of Colorado School of Medicine Jan. 1, 1911, when the clinical year of the latter school will be removed to Denver. Fees for each of the last two years, respectively, are \$103 and \$126. The Dean is Dr. George H. Stover, 1443 Glenard Place. The total registration for 1909-10 was 117; graduates, 21. The thirtieth session begins Sept. 12, 1910, and ends June 7, 1911.

CONNECTICUT

Connecticut, with a population of 1,054,336, has only one medical college, located in New Haven, population 127,827.

New Haven

YALE MEDICAL SCHOOL, York and Chapel Streets.—This is the Department of Medicine of Yale University. In 1810 a charter was granted for the establishment of this school, and 1813 it was organized as the Medical Institution of Yale College. The first class graduated in 1814. The faculty consists of 16 professors and 50 lecturers and assistants, a total of 66. The requirement for admission is two full years of collegiate work plus evidence of satisfactory preparation in physics, general inorganic chemistry and general biology. The course covers four years of nine months each. The fees are \$150 each year; in the first year there are additional fees amounting to \$23, and in the second \$3, and there is a graduation fee of \$10. The Dean is Dr. George Blumer, New Haven. The total registration for 1909-10 was 124; graduates, 27. The ninety-eighth session begins Sept. 29, 1910, and ends June 21, 1911.

DISTRICT OF COLUMBIA

Washington, population 322,212, has three medical colleges; George Washington University Department of Medicine, Georgetown University School of Medicine and Howard University Medical Department.

Washington

GEORGE WASHINGTON UNIVERSITY, DEPARTMENT OF MEDICINE, 1325 H Street, N.W.—Organized in 1825 as the National Medical College, Medical Department of Columbian College. Classes were graduated in 1826 and in all subsequent years, except 1834 to 1838, and 1861 to 1863, inclusive. The original title was changed in 1838, and 1861 to 1863, inclusive. The original title was changed to Medical Department of Columbian University in 1873. In 1904, by an act of Congress, it received its present title. The faculty is composed of 35 professors and 46 instructors, demonstrators and assistants, a total of 81. The course covers four years of eight

months each. The total fees are \$150 per year. The Dean is Dr. William C. Borden. The total registration for 1909-10 was 115; graduates, 26. The 89th session begins Sept. 28, 1910, and ends June 7, 1911.

GEORGETOWN UNIVERSITY, SCHOOL OF MEDICINE, 920 H Street, N.W.—Organized in 1851. The first class graduated in 1852. The faculty contains 20 professors, 54 instructors and assistants; total 74. The course of study covers four terms of eight and one-half months each. The fees are \$150 each year. The Dean is Dr. George M. Kober, 1600 T Street. The registration for 1909-10 was 117; graduates, 14. The sixtieth session begins Sept. 26, 1910, and ends June 11, 1911.

HOWARD UNIVERSITY, MEDICAL DEPARTMENT, Fifth and W Streets, N.W.—Chartered in 1867. Organized in 1869. The first class graduated in 1871. Colored students compose a majority of those in attendance. The faculty comprises 23 professors and 23 lecturers and assistants, 46 in all. The course covers four years of thirty weeks each. The fees of each session are \$100, plus \$7 for graduation. The Dean is Dr. Edward A. Balloch. Registration for 1909-10 was 210; graduates, 30. The forty-third session begins Oct. 1, 1910, and ends May 25, 1911.

GEORGIA

Georgia, population 2,557,412, has five medical colleges; Medical College of Georgia, located in Augusta, population 44,967; Atlanta College of Physicians and Surgeons, Atlanta School of Medicine, the Georgia College of Eclectic Medicine and Surgery, and the Hospital Medical College are in Atlanta, a city of 111,825 population.

Atlanta

ATLANTA COLLEGE OF PHYSICIANS AND SURGEONS, Butler and Armstrong Streets.—Organized in 1898 by union of the Atlanta Medical College, organized in 1855, and Southern Medical College, organized in 1878. The first class graduated in 1899. It has a faculty of 24 professors and 31 assistants, a total of 55. The course of study covers four years of seven months each. Fees: \$100 each year. The Dean is Dr. W. S. Elkin, 29 Luckie Street. Total registration of students for 1909-10 334; graduates, 63. The thirteenth session begins Sept. 21, 1910, and ends May 2, 1911.

ATLANTA SCHOOL OF MEDICINE, Luckie, Barton and Cain Streets.—Organized in September, 1905. The first class graduated in 1906. The course covers four years of seven months each. It has a faculty of 13 professors and 27 lecturers and assistants, a total of 40. The fees for each of the first two years are \$70; for each of the last two, \$80. The Proctor is Dr. Edward G. Jones. The total registration for 1909-10 was 227; graduates, 42. The sixth session begins Sept. 20, 1910, and ends April 20, 1911.

GEORGIA COLLEGE OF ECLECTIC MEDICINE AND SURGERY, Tanner Street, near Edgewood Avenue.—Organized in 1877 as the Georgia Eclectic Medical College. In 1884 it acquired the charter of the College of American Medicine and Surgery. It assumed its present name in 1886. The first class graduated in 1878. The faculty consists of 14 professors and 6 assistants, a total of 20. Tuition is \$80 per year; graduation fee, \$25. The Proctor is Dr. E. B. Thomas. Total registration for 1909-10 was 90; graduates, 35. The next session begins Sept. 21, 1910, and ends April 21, 1911.

HOSPITAL MEDICAL COLLEGE, Eclectic, Capitol Avenue and Richardson Street.—Organized in 1908. The faculty consists of 16 professors, and 8 lecturers and assistants, a total of 24. The tuition fees are \$80 each year; graduation fee, \$30. The Dean is Dr. William Bernard Lingo. Total registration for 1909-10 was 43; graduates, 15. The next session begins Sept. 15, 1910, and ends April 1, 1911.

Augusta

MEDICAL COLLEGE OF GEORGIA, Sixth and Telfair Streets.—Organized in 1828 as the Medical Academy of Georgia, the name being changed to the Medical College of Georgia in 1829. Since 1873 it has been known as the Medical Department of the University of Georgia. Classes were graduated in 1833 and in all subsequent years, except 1862 and 1863. The faculty includes 17 professors and 17 assistants, 34 in all. The course is four years of seven months each. Fees for each of the four years are \$100. The Dean is Dr. W. H. Doughty, Jr. The total registration for 1909-10 was 113; graduates, 13. The seventy-ninth session begins Oct. 1, 1910, and ends May 1, 1911.

ILLINOIS

Illinois, population 5,717,229, has eleven medical colleges, two of which are night schools, all located in Chicago, a city of 2,224,491 inhabitants, and are as follows: Rush Medical College, Northwestern University Medical School, College of Physicians and Surgeons, Hahnemann Medical College, Bennett Medical College, Hering Medical College, Jenner Medical College, American Medical Missionary College, College of Medicine and Surgery, Chicago College of Medicine and Surgery and Reliance Medical College.

Chicago

RUSH MEDICAL COLLEGE.—This school was founded in 1837, organized in 1843, was the medical department of Lake Forest University from 1887 until 1898, when it became affiliated with the University of Chicago. The first class graduated in 1844. The faculty is composed of 88 professors, 181 associates, instructors, etc., a total of 269. The requirements for admission are a four-year high school education and, in addition thereto, two years of college work, including courses in college chemistry, physics and biology, and a reading knowledge of German or French. The course covers four years of eight and a half months each. An optional fifth year, consisting of a hospital internship or of a fellowship in

one of the departments is offered. All freshmen and sophomore studies are given at the University of Chicago. The last two years are given in the clinical building at the corner of Wood and Harrison Streets. The total fees are \$180 each year. A matriculation fee of \$5 is paid but once, and there are incidentals amounting to from \$2 to \$5 annually. The Dean is Dr. John M. Dodson, 34 Washington Street. Total registration 1909-10 was 468; graduates, 85. The sixty-eighth session begins Oct. 1, 1910, and ends June 17, 1911.

NORTHWESTERN UNIVERSITY MEDICAL SCHOOL. Dearborn Street, between Twenty-fourth and Twenty-fifth Streets.—Organized in 1859 as the Medical Department of Lind University. In 1864 it became independent as the Chicago Medical College. It united with Northwestern University in 1869, but retained the name of Chicago Medical College until 1891, when the present name was taken. The faculty comprises 53 professors and 110 lecturers and assistants, a total of 163. The requirements for admission are such as will admit to the College of Liberal Arts of Northwestern University plus one year of college work including courses in physics, chemistry, biology and modern languages. The course covers four years of thirty weeks each. The fees for the first year are \$190; second year, \$200; third year, \$191.50, and fourth year, \$185. The Secretary is Dr. Charles Louis Mix. The total registration for 1909-10 was 637; graduates, 142. The fifty-first session begins Oct. 4, 1910, and ends May 29, 1911.

COLLEGE OF PHYSICIANS AND SURGEONS, Honore and Congress Streets.—Organized in 1882. The first class graduated in 1883. It became the Medical Department of the University of Illinois in 1896. The faculty is composed of 47 professors, 103 assistants and instructors, a total of 150. The fees are \$155 each for the first two years, \$150 for the third, and \$175 for the fourth year. The Dean is Dr. William E. Quine, 103 State Street. Total registration for 1909-10 was 526; graduates, 131. The twenty-ninth session begins Sept. 27, 1910, and ends June 7, 1911.

AMERICAN MEDICAL MISSIONARY COLLEGE, 888 Thirty-fifth Place.—Organized in 1895. The first class graduated in 1899. Part of the work is given at Battle Creek, Michigan. The faculty numbers 22 professors and 10 assistants, a total of 32. The course covers four years of nine months each. Total fees for the four years, respectively, are \$182, \$182, \$175, \$175. The Registrar is Dr. Benton N. Colver, Battle Creek, Mich. Total registration for 1909-10 was 67; graduates, 9. The sixteenth session opens Sept. 13, 1910, and closes June 9, 1911.

CHICAGO COLLEGE OF MEDICINE AND SURGERY, 337 South Lincoln Street.—Organized in 1901 as the American College of Medicine and Surgery (Chicago Eclectic Medical College). The latter part of the name was dropped in 1902 when it became the Medical Department of Valparaiso University. Eclecticism was dropped in 1905. The name was changed to the above in 1907. The course covers four years of eight months each. The faculty consists of 39 professors and 34 lecturers and assistants, a total of 73. The total fees for each of the four years, respectively, are \$120, \$110, \$100 and \$100. The Registrar is Dr. G. E. Wyneken. The total registration for 1909-10 was 580; graduates, 89. The tenth session begins Sept. 27, 1910, and ends May 15, 1911.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL OF CHICAGO, 2811 Cottage Grove Avenue.—Organized in 1859. The first class was graduated in 1861. The faculty includes 38 professors and 46 lecturers, assistants, etc., a total of 84. The course extends over four years of eight months each. The tuition fees are \$100 each year. The Registrar is Dr. W. Henry Wilson. The total registration for 1909-10 was 131; graduates, 31. The fifty-first session begins Sept. 27, 1910, and ends May 25, 1911.

HEBER MEDICAL COLLEGE, Homeopathic, Wood and York Streets.—Organized in 1892. The first class graduated in 1893. The faculty consists of 29 professors and 23 assistants, instructors, etc., a total of 52. The tuition fees are \$100 per year. The Dean is Dr. Robert N. Morris. The total registration for 1909-10 was 42; graduates, 12. The next session begins Sept. 27, 1910, and ends June 1, 1911.

BENNETT MEDICAL COLLEGE, MEDICAL DEPARTMENT OF LOYOLA UNIVERSITY, Fulton and Ada Streets.—Organized in 1868 as the Bennett College of Eclectic Medicine and Surgery. Dropped Eclecticism in 1909. In 1910 the Illinois Medical College merged with it and it became the Medical Department of Loyola University. The first class graduated in 1870. The faculty numbers 57. The course covers four years of thirty weeks each. Fees for each year are \$125, with a matriculation fee, paid once, of \$5. The President is Dr. John D. Robertson. The total registration for the two colleges in 1909-10 was 231; graduates, 37. The next session begins Sept. 20, 1910, and ends May 31, 1911.

COLLEGE OF MEDICINE AND SURGERY, Physiomedical, 721-725 South Wood Street.—Organized in 1885 as the Chicago Physiomedical Institute. The first class graduated in 1886. In 1891 the name was changed to the Chicago Physiomedical College. In 1899 it took its present name. The faculty numbers 61. The school year has three divisions of 16 weeks each. Attendance on any two will constitute a year's work. Fees for the four years, respectively, are \$120, \$115, \$115 and \$140. The Secretary is Dr. William F. Schaare. The total registration for 1909-10 was 57; graduates, 16. The next session begins Sept. 21, 1910, and ends May 12, 1911.

JENNER MEDICAL COLLEGE, a night school located at 196 East Washington Street.—Organized in 1892. Classes were graduated in 1896 and in all subsequent years. The faculty numbers 50. Registrar, Dr. John D. MacKellar. Total registration for 1909-10 was 205; graduates, 23. The next session begins Aug. 29, 1910, and ends June 30, 1911.

RELIANCE MEDICAL COLLEGE. A night school, located at Washington Boulevard and Halsted Street.—Organized in 1907. The faculty numbers 65. The total fees are \$130 for each of the first two years and \$125 for each of the last two. Registration for 1909-10 was 80; graduates, 7. The President is Dr. J. F. Burkholder. The next session begins Sept. 1, 1910, and ends June 27, 1911.

INDIANA

Indiana, population 2,808,115, has one medical college, the Indiana University School of Medicine, located at Indianapolis, a city of 241,826 people, except that the work of the first two years is offered also at Bloomington, population 5,000, the seat of the University.

Bloomington and Indianapolis

INDIANA UNIVERSITY SCHOOL OF MEDICINE.—Organized in 1893, but did not give all of the work of the first two years of the medical course until 1905. In 1907, by union with the State College of Physicians and Surgeons, the complete course in medicine was offered. In 1908 the Indiana Medical College, which was formed in 1907 by the merger of the Medical College of Indiana (organized in 1869) and the Fort Wayne College of Medicine (organized in 1879) merged into it. The faculty consists of 100 professors and 89 lecturers, associates and assistants, a total of 189. Two years of collegiate work are required for admission. The work of the first two years may be taken either at Bloomington or at Indianapolis. The clinical work is all done at Indianapolis. A fifth optional year leading to the "M.D. cum laude" has been added. The Secretary at Bloomington is Dr. B. D. Myers; at Indianapolis, Dr. Edmund D. Clark, Newton-Claypool Bldg. The total registration for 1909-10 was 248; graduates, 59. The next session begins Sept. 22, 1910, and ends June 16, 1911.

IOWA

Iowa, population 2,192,608, has three medical colleges. The College of Medicine of the State University of Iowa and the College of Homeopathic Medicine of the State University of Iowa are located in Iowa City, population 8,197. In Des Moines, population 86,415, is the College of Medicine of Drake University.

Des Moines

DRAKE UNIVERSITY COLLEGE OF MEDICINE.—First two years given on the University Campus, University Avenue, between Twenty-fifth and Twenty-eighth Streets, the clinical years at Fourth and Center Streets. Organized in 1882 as the Iowa College of Physicians and Surgeons. The first class graduated in 1883. In 1887 it became affiliated with and in 1900 became the Medical Department of Drake University. The faculty consists of 20 professors and 30 assistants, lecturers, etc., a total of 50. Two years of collegiate work, including courses in physics, chemistry and histology, are required for admission. The work covers four years of nine months each. The total fees are \$150 each year. The Dean is Dr. William Wilson Pearson. The total registration for 1909-10 was 108; graduates, 23. The twenty-eighth session begins Sept. 19, 1910, and ends June 14, 1911.

Iowa City

STATE UNIVERSITY OF IOWA COLLEGE OF MEDICINE. University Campus.—Organized in 1869. First session began in 1870. First class graduated in 1871. The faculty is made up of 15 professors, 25 lecturers, demonstrators and assistants, a total of 40. Two years of collegiate work, including courses in physics, chemistry and biology, are required for admission. The course of study covers four years of thirty-six weeks each. Total fees for each year are \$50 plus a matriculation fee of \$10 paid but once and a graduation fee of \$10. The Dean is Dr. James R. Guthrie, Dubuque. Total number of students registered for 1909-10 was 190; graduates, 44. The forty-first session begins Sept. 19, 1910, and ends June 14, 1911.

STATE UNIVERSITY OF IOWA COLLEGE OF HOMEOPATHIC MEDICINE.—Organized in 1877. The first class graduated in 1878. The faculty is composed of 11 professors and 19 lecturers and assistants, a total of 30. The work of the first two years is taken in classes with the students of the College of Medicine of the State University of Iowa, and it has the same entrance requirements. The fees are \$50 each year, plus a matriculation fee of \$10, paid but once and a graduation fee of \$10. The Dean is Dr. George Royal. Total registration for 1909-10 was 35; graduates, 7. The thirty-third session begins Sept. 19, 1910, and ends June 14, 1911.

KANSAS

Population 1,703,002, has two medical colleges. Kansas Medical College is in Topeka, population 44,757. The School of Medicine of the University of Kansas gives its first two years in Lawrence, population 12,915, and the last two years in Rosedale, a suburb of the two Kansas Cities, which together have a population of 277,427.

Lawrence and Kansas City

UNIVERSITY OF KANSAS SCHOOL OF MEDICINE.—Organized in 1880. In 1905 it merged with the Kansas City (Mo.) Medical College, founded in 1869, the College of Physicians and Surgeons, founded in 1894, and the Medico-Chirurgical College, founded in 1897. The faculty, including lecturers and clinical assistants, numbers 87. The requirements for admission are two years of collegiate work. The course covers four years of about nine months each. The total fees are, for the first two years, \$60 per year (and for non-residents of the state, \$70); for the last two years, \$100 and \$110, respectively. The Dean at Lawrence is Dr. Mervin T. Sudler. The Dean at Kansas City is Dr. George Howard Hoxie. The total registration for 1909-10 was 89; graduates, 20. The thirty-first session begins Sept. 19, 1910, and ends June 7, 1911.

Topeka

KANSAS MEDICAL COLLEGE, 521 Quincy Street.—Organized in 1890. The first class graduated in 1892. It has been the Medical Department of Washburn College since 1903. It has a faculty of 26 professors and 18 lecturers and assistants, a total of 44. The course covers four years of nine months each. Fees, \$75 yearly. Matriculation fee of \$5 paid but once. The Dean is Dr. William E. McVey. Total registration for 1909-10 was 67; graduates, 12. The twenty-first session begins Sept. 14, 1910, and ends June 7, 1911.

KENTUCKY

Kentucky, population 2,406,859, has three medical colleges. They are all situated in Louisville, a city of 236,688 inhabitants, and are as follows: University of Louisville Medical Department, Southwestern Homeopathic Medical College and Louisville National Medical College.

Louisville

UNIVERSITY OF LOUISVILLE MEDICAL DEPARTMENT, Eighth and Chestnut Streets.—Organized in 1837 as the Louisville Medical Institute. The first class graduated in 1838, and a class graduated in each subsequent year except 1863. In 1846 the present name was assumed. In 1907 it absorbed the Kentucky University Medical Department. In 1908 it absorbed the Louisville Medical College, the Hospital College of Medicine and the Kentucky School of Medicine. It has a faculty of 42 professors and 50 lecturers and assistants, a total of 92. The course covers four years of thirty weeks each. The fees are \$105 each year; graduation fee, \$25. The Dean is Dr. T. C. Evans. The total registration for 1909-10 was 624; graduates, 202. The next session begins Oct. 10, 1910, and ends May 19, 1911.

SOUTHWESTERN HOMEOPATHIC MEDICAL COLLEGE AND HOSPITAL, Floyd and Walnut Streets.—Organized in 1892. The first class graduated in 1894. It has a faculty of 12 professors and 15 lecturers and assistants, 27 in all. The curriculum covers four years of seven months each. Total fees: First three years \$80 each and \$100 for the fourth. The Dean is Dr. George S. Coon. Total number of students for 1909-10 was 13; graduates, 2. The eighteenth session begins Oct. 6, 1910, and ends May 25, 1911.

LOUISVILLE NATIONAL MEDICAL COLLEGE, Colored. 112 West Green Street.—Organized in 1888. The first class graduated in 1889. The faculty numbers 23. The course covers four years of seven months each. The fees are \$60, \$55, \$55 and \$75 for the four years, respectively. The Dean is Dr. E. S. Porter. Total registration for 1909-10 was 31; graduates, 8. The next session begins Oct. 1, 1910, and ends May 18, 1911.

LOUISIANA

Louisiana, having a population of 1,618,358, contains two medical colleges: Medical Department of the Tulane University of Louisiana and Flint Medical College of New Orleans University. They are both situated in New Orleans, a city of 327,662 people.

New Orleans

MEDICAL DEPARTMENT OF THE TULANE UNIVERSITY OF LOUISIANA, University Campus and 1551 Canal Street.—Organized in 1834 as the Medical College of Louisiana. Classes were graduated in 1835 and in all subsequent years, except 1863-65, inclusive. It was transferred to Medical Department of the University of Louisiana in 1847 and became the Medical Department of the Tulane University in 1884. The faculty numbers 73. The course covers four years of thirty-two weeks each. One year of collegiate work is required for admission. Total fees are \$160 per year. The Dean is Dr. Isadore Dyer. The total registration for 1909-10 was 417; graduates, 103. The seventy-seventh session begins Oct. 1, 1910, and ends June 1, 1911.

FLINT MEDICAL COLLEGE OF NEW ORLEANS UNIVERSITY, Colored. 1506 Canal Street.—Organized in 1889 as the Medical College of New Orleans University. A class was graduated in 1892 and in each subsequent year, except 1896. Took the above name in 1901. The faculty numbers 15. The course covers four years of thirty weeks each. Total fees for each of the four years, respectively, are \$60, \$56, \$50 and \$50. The Dean is Dr. R. T. Fuller. Total registration for 1909-10 was 19; graduates, 4. The twenty-first session begins Sept. 29, 1910, and ends May 9, 1911.

MAINE

Maine, population 724,508, has one medical college, located in Brunswick and Portland, the latter having a population of 57,675.

Brunswick-Portland

MEDICAL SCHOOL OF MAINE. The medical department of Bowdoin College. The first two years are given at Bowdoin College, Brunswick, the last two at Portland, building located on Chadwick Street.—Organized in 1820. The first class graduated in 1820. The faculty numbers 37. The course covers four years of eight months each. The total fees are \$120 for the first year and \$110 for each of the other three years. The Dean is Dr. Alfred Mitchell, Brunswick. Total number of students in 1909-10 was 74; graduates, 20. The nineteenth session begins Oct. 13, 1910, and ends June 21, 1911.

MARYLAND

Maryland, with a population of 1,319,132, contains six medical colleges, all located in Baltimore, a city with 576,023 inhabitants. They are as follows: Johns Hopkins University Medical Department, School of Medicine of the University of Maryland, College of Physicians and Surgeons, Baltimore Medical College, Atlantic Medical College and Maryland Medical College.

Baltimore

JOHNS HOPKINS UNIVERSITY, MEDICAL DEPARTMENT, Washington and Monument Streets.—Organized in 1893. The first class graduated in 1897. The faculty consists of 23 professors and 89 clinical professors, etc., a total of 112. The requirements for admission demand that the applicant either has (a) completed the chemical-biologic course which leads to the A.B. degree in the university or (b) graduated at an approved college or scientific school and has a knowledge of French and German, physics, chemistry and biology, such as may be obtained from a year's course. The course extends over four years of eight and one-half months each. The charge for tuition is \$200 per annum. The Dean is Dr. William H. Howell, 232 West Lanvale Street. Total registration for 1909-10 was 334; graduates, 72. The eighteenth session begins Oct. 5, 1910, and ends June 14, 1911.

COLLEGE OF PHYSICIANS AND SURGEONS, Calvert and Saratoga Streets.—Organized in 1872. The first class graduated in 1873. In 1878 it united with Washington University School of Medicine. The faculty numbers 58. The work covers four years of eight months each. Total fees are \$155 for each of the first three years and \$185 for the fourth year. The Dean is Dr. Charles F. Bevan. The total number of students registered in 1909-10 was 283; graduates, 66. The thirty-ninth session begins Oct. 1, 1910, and ends June 1, 1911.

UNIVERSITY OF MARYLAND SCHOOL OF MEDICINE, Lombard and Greene Streets.—Organized in 1807 as the College of Medicine of Maryland. The first class graduated in 1810. In 1812 it became the University of Maryland School of Medicine. The faculty numbers 62. The course covers four years of eight months each. The total fees are \$155 each year; graduation fee, \$30. The Dean is Dr. R. Dorsey Coale. The total number of students registered in 1909-10 was 309; graduates, 85. The 104th session begins Oct. 1, 1910, and ends June 1, 1911.

BALTIMORE MEDICAL COLLEGE, Madison Street and Linden Avenue.—Organized in 1881. The first class graduated in 1882. The faculty numbers 71. The course covers four years of eight months each. Total fees for the first three years are \$125 per year; for the fourth year, \$155. The Dean is Dr. David Streett. The total number of students registered in 1909-10 was 270; graduates, 54. The twenty-ninth session begins Sept. 20, 1910, and ends May 27, 1911.

MARYLAND MEDICAL COLLEGE, 1114 West Baltimore Street.—Organized in 1898. The first class graduated in 1899. The faculty numbers 38. The course covers four years of eight months each. Total fees for the four years, respectively, are \$111, \$111, \$105 and \$135. The Dean is Dr. W. S. Smith. The total registration for 1909-10 was 112; graduates, 36. The next session begins Oct. 1, 1910, and ends June 1, 1911.

ATLANTIC MEDICAL COLLEGE, Mount Street, north of Riggs Avenue.—Organized in 1891 as the Southern Homeopathic Medical College. In 1907 it assumed the above name and became "non-sectarian." The Dean is Dr. Eldridge C. Price. The total registration for 1909-10 was 19, of which number 14 graduated. Among these graduates are several who are reported as having failed miserably in other medical colleges.

MASSACHUSETTS

Massachusetts, population 3,162,347, has four medical colleges: Medical School for Harvard University, Boston University School of Medicine, College of Physicians and Surgeons and Tufts College Medical School. They are all situated in Boston, a city of 622,970.

Boston

MEDICAL SCHOOL OF HARVARD UNIVERSITY, Longwood Avenue.—Organized in 1782. The first class graduated in 1788. It has a faculty of 35 professors and 136 associates, assistants, etc., a total of 171. Candidates for admission "must present a degree in arts, literature, philosophy or science from a recognized college or scientific school, with the exception of such persons as may be admitted by special vote of the faculty." The session is four years of eight months each. Fees: Matriculation, \$5; tuition, \$200 each year. The Dean is Dr. Henry A. Christian. The total registration for 1909-10 was 279; graduates, 66. The 120th session begins Sept. 29, 1910, and ends June 1, 1911.

BOSTON UNIVERSITY SCHOOL OF MEDICINE, 80 East Concord Street.—Organized in 1873. In 1874 the New England Female Medical College, founded in 1848, was merged into it. The first class graduated in 1874. The faculty includes 27 professors, 39 associates, etc., a total of 66. The course covers four years of eight months each. Total fees for the first, second and third years, \$127 each, and for the last year, \$155. The Dean is Dr. John P. Sutherland, 302 Beacon Street. Total registration for 1909-10 was 79; graduates, 14. The thirty-eighth session begins Oct. 6, 1910, and ends June 7, 1911.

TUFTS COLLEGE MEDICAL SCHOOL, 416 Huntington Avenue.—Organized in 1893 as the Medical Department of Tufts College. The first class graduated in 1894. It has a faculty of 33 professors and 70 assistants, lecturers, etc., a total of 103. The course covers four years of eight months each. The total fees are \$155 each year. The Secretary is Dr. Frederic M. Briggs, 31 Massachusetts

Avenue. Total number of students for 1909-10 was 428; graduates, 52. The seventeenth session begins Sept. 28, 1910, and ends June 1, 1911.

COLLEGE OF PHYSICIANS AND SURGEONS, 517 Shawmut Avenue.—Organized in 1880. The first class graduated in 1882. The course covers four years of nine months each. The college announcement gives the names of 226 "matriculants and applicants" for the session of 1908-9, which included both dental and medical students. From other reliable information it seems that only about 80 medical students actually attended throughout the session of 1909-10. There were 28 graduates reported. The faculty numbers 56. The Dean is Dr. Thomas D. Crothers. The next session begins Sept. 21, 1910, and ends June 14, 1911.

MICHIGAN

Michigan, population 2,666,308, has four medical colleges. Two of these, the University of Michigan Department of Medicine and Surgery and the Homeopathic College of the University of Michigan, are located at Ann Arbor, a city of 14,711 people. Detroit, a city of 384,855 inhabitants, contains two medical colleges, the Detroit College of Medicine and the Detroit Homeopathic College.

Ann Arbor

UNIVERSITY OF MICHIGAN DEPARTMENT OF MEDICINE AND SURGERY.—Organized in 1850. The first class graduated in 1851. It has a faculty composed of 18 professors, 36 associates, instructors, etc., a total of 74. The entrance requirements are two years of college work, including courses in chemistry, physics and biology, with laboratory work, and a reading knowledge of one modern language. The curriculum embraces four years of nine months each. The total fees for Michigan students for the entire course of four years is \$350 and for others about \$400. The Dean is Dr. Victor C. Vaughan. The total registration for 1909-10 was 315; graduates, 64. The sixty-first session begins Oct. 4, 1910, and ends June 29, 1911.

UNIVERSITY OF MICHIGAN HOMEOPATHIC COLLEGE.—Organized in 1875. The first class graduated in 1877. Although the work of the first two years is taken in the same classes with the Department of Medicine and Surgery of the University of Michigan, nevertheless the entrance requirements are still kept at only a high-school education—a difference of two years of collegiate work! The Dean is Dr. W. B. Hinsdale. The total registration for 1909-10 was 74; graduates, 11. The next session begins Oct. 4, 1910, and ends June 29, 1911.

Detroit

DETROIT COLLEGE OF MEDICINE, St. Antoine, Catherine and Mullett Streets and Gratiot Avenue.—Organized in 1885 by consolidation of Detroit Medical College, organized in 1868, and the Michigan College of Medicine, organized in 1880. The first class graduated in 1886. The faculty embraces 25 professors, 88 lecturers, instructors, etc., a total of 113. The course covers four years of eight months each. The Registrar is Dr. F. B. Walker. The total registration for 1909-10 was 152; graduates, 38. The twenty-sixth session begins Sept. 21, 1910, and ends May 25, 1911.

DETROIT HOMEOPATHIC COLLEGE, Lafayette Avenue and Third Street.—Organized in 1899. A class was graduated in 1900 and in each subsequent year. It has a faculty of 36. The course embraces four years of eight months each. Fees: From \$75 to \$95 per year. The Registrar is Dr. Fred E. Thompson. The total registration for 1909-10 was 26; graduates, 5. The twelfth session begins Sept. 14, 1910, and ends May 19, 1911.

MINNESOTA

Minnesota, population 2,162,726, contains one medical college, the College of Medicine and Surgery of the University of Minnesota, situated in Minneapolis. Minneapolis and St. Paul are practically one city, and have a combined population of 477,640.

Minneapolis

UNIVERSITY OF MINNESOTA COLLEGE OF MEDICINE AND SURGERY.—Organized in 1883; reorganized in 1888 by absorption of St. Paul Medical College and Minnesota Hospital Medical College. The first class graduated in 1889. In 1908 the Minneapolis College of Physicians and Surgeons, organized in 1883, was merged. In 1909 the Homeopathic College of Medicine and Surgery was merged and provision made for elective chairs in didactic materia medica and therapeutics. Students electing these courses on graduation will receive the degree of Doctor of Medicine in Homeopathy. The faculty includes 61 professors and clinical professors and 67 associate professors, assistants, etc., a total of 128. The curriculum covers four years of nine months each. The entrance requirements are two years of university work which must include one year each of physics, general chemistry, qualitative analysis, zoology or botany, and German or French, all in addition to a four-year high school course, including Latin. Total fees for the first year are \$150, for each of the other years \$100; microscope rental, \$1 to \$4 per annum. The Dean is Dr. F. F. Westbrook. The total registration for 1909-10 was 176, including 16 Hamline University students; the graduates of 1910 numbered 34, including 3 which were granted degrees by Hamline University. The twenty-third session begins Sept. 13, 1910, and ends June 8, 1911.

MISSISSIPPI

Mississippi, population 1,786,773, has two medical colleges, the Medical Department of the University of Mississippi giving only the first two years of the medical course, is located at

Oxford, a city of 1,825 inhabitants. The Mississippi Medical College is located at Meridian, population 21,937.

Meridian

MISSISSIPPI MEDICAL COLLEGE, Fifth Street and Twenty-fourth Avenue.—Organized in 1906. The first class graduated in 1907. The faculty numbers 25. The course covers four years of seven months each. The Secretary is Dr. W. W. Hamilton. The total registration for 1909-10 was 96; graduates, 18. The fifth session begins Oct. 3, 1910, and ends April 30, 1911.

Oxford

UNIVERSITY OF MISSISSIPPI MEDICAL DEPARTMENT.—Organized in 1903. Gave only the first two years of the medical course until 1909, when a clinical department was organized at Vicksburg. Graduated one class in 1910, when the clinical years of the course were discontinued. The course covers four years of eight and a half months each. The work of the first two years is given at Oxford. The faculty numbers 30. The Dean is Dr. W. S. Leathers. The total registration for 1909-10 was 49; graduates, 4. The eighth session begins Sept. 23, 1910, and ends June 1, 1911.

MISSOURI

Missouri, population 3,491,397, has ten medical colleges. St. Louis, population 686,369, contains five of these, viz., St. Louis College of Physicians and Surgeons, American Medical College, the School of Medicine of St. Louis University, Washington University Medical Department and Barnes Medical College. Kansas City, which with Kansas City, Kan., has a total population of 277,427, has three colleges, namely: University Medical College, the Kansas City Hahnemann Medical College and the Eclectic Medical University. Ensworth Medical College is located in St. Joseph, population 125,504. The Department of Medicine of the University of Missouri is at Columbia, a town of 5,651 people.

Columbia

UNIVERSITY OF MISSOURI SCHOOL OF MEDICINE.—Organized at St. Louis in 1845; was discontinued in 1859, but was reorganized at Columbia in 1872. Teaching of the clinical years was suspended in 1909. The faculty includes 10 professors, 8 assistant professors, lecturers, etc., a total of 18. The course covers two years of nine months each. The entrance requirements are two years of college work, including English, 5 hours; German, 5 hours; general zoology, 5 hours; physics, 5 hours; inorganic chemistry, 5 hours; Elective, 35 hours. Equivalent work in foreign language may be substituted for the English and German. Total fees are \$70 each year. The Dean is Dr. C. M. Jackson. Total registration of students for 1909-10 was 29. The next session begins Sept. 22, 1910, and ends June 8, 1911.

Kansas City

UNIVERSITY MEDICAL COLLEGE OF KANSAS CITY, 911 East Tenth Street.—Organized in 1881 as the University of Kansas City Medical Department. The first class graduated in 1882. It was reorganized in 1888 under the present title. Its faculty comprises 47 professors and 19 lecturers and assistants, a total of 66. The course of study covers four years of thirty weeks each. The total fees for each year are \$100; graduation fee, \$25. The Dean is Dr. J. M. Frankenburger. The total registration for 1909-10 was 186; graduates, 48. The twenty-ninth session begins Sept. 6, 1910, and ends May 15, 1911.

KANSAS CITY HAHNEMANN MEDICAL COLLEGE, 1020 East Tenth Street.—Organized in 1888 as the Kansas City Homeopathic Medical College. The first class graduated in 1899. In 1902 it united with the Hahnemann Medical College of the Kansas City University, taking the present title. The Dean is Dr. William E. Cramer. Total registration for 1909-10 was 58; graduates, 21. The next session begins Sept. 7, 1910, and ends May 6, 1911.

ECLECTIC MEDICAL UNIVERSITY, 1423 Independence Avenue.—Organized at Kansas City, Mo., in 1898 with the present title. Moved to Kansas City, Kan., in 1907, and took the name of Western Eclectic College of Medicine and Surgery. Returned to Kansas City, Mo., in 1909 and resumed the present title. First class graduated in 1900. The faculty numbers 32. Fees for the four years, respectively, are \$90, \$95, \$100 and \$115. Course covers four years of about eight months each. The Secretary is Dr. M. D. L. Isley. The total registration for 1909-10 was 21; graduates, 9. The thirteenth sessions begins Sept. 6, 1910, and ends April 30, 1911.

St. Joseph

THE ENSWORTH MEDICAL COLLEGE, Seventh and Jule Streets.—Organized in 1876 as the St. Joseph Hospital Medical College. In 1882 it merged with the College of Physicians and Surgeons to form the St. Joseph Medical College. In 1888 changed name to Ensworth Medical College. In 1905 merged with the Central Medical College, organized in 1894, to form the Ensworth-Central Medical College. In 1907 the present title was resumed. The faculty numbers 34. The course covers four years of thirty weeks each. The fees for the four years, respectively, are \$90, \$95, \$75 and \$95. The Secretary is Dr. T. E. Potter. Total registration for 1909-10 was 68; graduates, 17. The next session begins Sept. 14, 1910, and ends May 1, 1911.

St. Louis

WASHINGTON UNIVERSITY MEDICAL SCHOOL, 1806 Locust Street.—Organized in 1842 as the Medical Department of St. Louis University. In 1855 it was chartered as an independent institution under the name of St. Louis Medical College. The first class graduated in 1843. In 1891 it became the Washington University

Medical School. In 1899 it absorbed the Missouri Medical College. The faculty comprises 48 professors, 51 lecturers and instructors, a total of 99. The course is four years of eight months each. The total fees for the four years are, respectively, \$137.50, \$132.25, \$117.25 and \$101.25. The Dean is Dr. George Dock. The total registration for 1909-10 was 205; graduates, 56. The next session begins Sept. 20, 1910, and ends June 8, 1911.

ST. LOUIS UNIVERSITY SCHOOL OF MEDICINE, Grand Avenue and Caroline Street.—Organized in 1901 by union of Marion-Sims Medical College, organized in 1890, and Beaumont Hospital Medical College, organized in 1886. It became the Medical Department of St. Louis University in 1903. The faculty is composed of 37 professors, 75 lecturers and assistants, a total of 112. The curriculum covers four years of eight months each. The total fees are \$110 each year. The Dean is Dr. E. P. Lyon. The total registration for 1909-10 was 261; graduates, 66. The next session begins Oct. 1, 1910, and ends May 29, 1911.

ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS, Jefferson Avenue and Gamble Street.—Organized in 1869. Classes graduated in 1870 and in each subsequent year until 1873, when it suspended. It was reorganized in 1879. Classes graduated in 1880 and subsequent years. It has a faculty of 25 professors, 24 lecturers, instructors, etc., a total of 49. The course covers four years of seven months each. Total fees for each of the four years, respectively, are \$105, \$100, \$100 and \$105. The Dean is Dr. Waldo Briggs, 2600 Gamble Street. Total registration for 1908-9 was 228; there were 42 graduates in 1910. The next session begins Sept. 15, 1910, and ends May 6, 1911.

BARNES MEDICAL COLLEGE, Garrison and Lawton Avenues.—Organized in 1892. Classes graduated in 1893 and in all subsequent years except 1899. The faculty consists of 40 professors and 8 lecturers and assistants, a total of 48. The course covers four years of eight months each. The total fees are \$100 each year. The Dean is Dr. A. R. Kieffer. Total registration for 1909-10 was 184; graduates, 51. The next session begins Sept. 14, 1910, and ends May 13, 1911.

AMERICAN MEDICAL COLLEGE, 407 South Jefferson Avenue.—Organized in 1873 as an Eclectic College. Eclecticism dropped in 1910. Two classes were graduated each year from 1874 to 1883, inclusive. Since then one class has graduated each year. The course covers four years of nine months each. The fees are \$100 each year. The Dean is Dr. James Moore Ball. The total registration for 1909-10 was 39; graduates, 7. The next session begins Sept. 5, 1910, and ends June 1, 1911.

NEBRASKA

Nebraska, population 1,069,579, has three medical colleges: The University of Nebraska College of Medicine and the John A. Creighton Medical College at Omaha, population 134,972, and the Lincoln Medical College at Lincoln, population 52,308.

Lincoln and Omaha

COLLEGE OF MEDICINE, UNIVERSITY OF NEBRASKA, Eleventh and R Streets, Lincoln, and Twelfth and Pacific Streets, Omaha.—Organized in 1881 as the Omaha Medical College. The first class graduated in 1882. It became the Medical Department of Omaha University in 1891. In 1902 it affiliated with the University of Nebraska, with the present title. Two years of collegiate work are required for admission. The first two years are given at Lincoln; the last two at Omaha. The faculty is composed of 28 professors and 40 lecturers and instructors, total 68. The fees are approximately \$100 per annum. Total registration for 1909-10 was 76; graduates, 16. The next session at Lincoln begins Sept. 20, 1910, and ends June 7, 1911. For the advanced classes at Omaha the next session begins Sept. 13, 1910, and ends May 27, 1911.

Lincoln

LINCOLN MEDICAL COLLEGE. Eclectic. Corner 13th and P Streets. It is the Medical Department of Cotner University.—Organized in 1890. The first class graduated in 1891. The faculty numbers 37. The course of study covers four years of thirty-two weeks each. The total fees are \$90 each year. The Secretary is Dr. R. H. Spradling, 1315 O Street. The total registration for 1909-10 was 58; graduates, 13. The twenty-first session begins Sept. 7, 1910, and ends May 20, 1911.

Omaha

JOHN A. CREIGHTON MEDICAL COLLEGE, Fourteenth and Davenport Streets. It is the Medical Department of Creighton University.—Organized in 1892. The first class graduated in 1895. It has a faculty of 31 professors and 18 associates, lecturers and assistants, a total of 49. The course of study embraces four years of eight months each. The total fees for the four years, respectively, are \$105, \$100, \$100 and \$105. The Dean is Dr. D. C. Bryant, McCague Building. Total number of students registered in 1909-10 was 194; graduates, 44. The nineteenth session begins Sept. 5, 1910, and ends April 29, 1911.

NEW HAMPSHIRE

New Hampshire, population 443,140, has one medical college, located at Hanover, population 1,884.

Hanover

DARTMOUTH MEDICAL SCHOOL.—Organized as New Hampshire Medical Institute in 1797. The first class graduated in 1798. It is the Medical Department of Dartmouth College. The faculty is made up of 17 professors and 6 instructors, a total of 23. Two years of collegiate work are required for admission. The course covers four years of eight months each. The fees are \$125 each year. The Dean is Dr. William T. Smith. The total registration for 1909-10 was 57; graduates, 10. The work of the first and

second years begins with that of the academic department Sept. 22, 1910, and ends June 24, 1911; for the advanced classes the course begins Aug. 2, 1910, and ends March 28, 1911.

NEW YORK

New York State, population 8,706,039, has eleven medical colleges. Eight of these, College of Physicians and Surgeons (Columbia University), Long Island College Hospital, New York Homeopathic Medical College and Hospital, New York Medical College and Hospital for Women, Eclectic Medical College of the City of New York, Cornell University Medical College, the University and Bellevue Hospital Medical College, and Fordham University School of Medicine, are located in New York City, population 4,450,963. Albany Medical College is located in Albany, a city of 100,730 people. The University of Buffalo Medical Department is situated in Buffalo, population of 396,535. The College of Medicine, Syracuse University, is in Syracuse, a city of 125,378 inhabitants.

Albany

ALBANY MEDICAL COLLEGE, Lancaster and Jay Streets.—Organized in 1838. The first class graduated in 1839. It became the Medical Department of Union University in 1873. The faculty is composed of 15 professors and 78 lecturers, assistants, etc., a total of 93. The curriculum covers four years of eight months each. Fees: First year, \$130; second year, \$145; third year, \$120, and fourth year, \$130. The Registrar is Dr. Willis G. Tucker. The total registration for 1909-10 was 196; graduates, 41. The eightieth session begins Sept. 20, 1910, and ends May 16, 1911.

Buffalo

UNIVERSITY OF BUFFALO MEDICAL DEPARTMENT, High Street, near Main.—Organized in 1846. The first class graduated in 1847. It absorbed the Medical Department of Niagara University in 1898. The faculty is composed of 37 professors and 58 lecturers, assistants, etc., a total of 95. The course covers four years of eight months each. The total fees for the four years, respectively, are \$185, \$180, \$140 and \$140. The Dean is Dr. Matthew D. Mann, 37 Allen Street. Total registration for 1909-10 was 191; graduates, 37. The sixty-fifth session begins Sept. 26, 1910, and ends June 1, 1911.

New York

COLUMBIA UNIVERSITY COLLEGE OF PHYSICIANS AND SURGEONS, 437 West Fifty-ninth Street.—Organized in 1807 by the regents of the University of the State of New York as their medical department. The first class graduated in 1811. Affiliated with Columbia College in 1814 and was permanently connected in 1860, when it became the Medical Department of Columbia College. That institution became Columbia University in 1891. The faculty is composed of 55 professors and 121 instructors, demonstrators, etc., a total of 176. Two years of collegiate work, including courses in physics, chemistry and biology are required for admission. The work covers four years of eight months each. The Dean is Dr. Samuel W. Lambert. The total fees for the first year are \$255; for the second and third, \$250, and \$275 for the fourth year. Total registration for 1909-10 was 360; graduates, 69. The 103d session begins Sept. 28, 1910, and ends June 7, 1911.

CORNELL UNIVERSITY MEDICAL COLLEGE, Ithaca, and First Avenue and Twenty-eighth Street, New York.—Organized in 1898. The first class was graduated in 1899. The work of the first year may be taken either in Ithaca or New York. The faculty is composed of 53 professors and 86 assistants, lecturers, instructors, etc., a total of 139. All candidates for admission must be graduates of approved colleges or scientific schools and in addition must have such knowledge of physics, inorganic chemistry and biology as may be obtained in college by a year's course in these subjects when accompanied by laboratory work. Fees: First year, \$190; second and third, \$185 each, and \$200 for the fourth year. The Dean is Dr. William M. Polk. Total registration for 1909-10 was 164; graduates, 68. The thirteenth session begins Sept. 28, 1910, and ends June 14, 1911.

ECLECTIC MEDICAL COLLEGE OF THE CITY OF NEW YORK, 239 East Fourteenth Street.—Organized in 1865. The first class graduated in 1867. The Dean is Dr. George W. Boskowitz. Total registration for 1909-10 was 91; graduates, 13.

FORDHAM UNIVERSITY SCHOOL OF MEDICINE, Third and Pelham Avenues.—Organized in 1905. First class graduated in 1909. The faculty consists of 47 professors and 31 lecturers and assistants, a total of 78. The course of instruction covers four years of nine months each. Fees, \$200 each year. A year's work in a recognized college of liberal arts is required for admission. The Dean is Dr. James J. Walsh. The total registration for 1909-10 was 75; graduates, 6. The sixth session begins Sept. 21, 1910, and ends June 15, 1911.

LONG ISLAND COLLEGE HOSPITAL, Henry Street, near Atlantic Avenue, Brooklyn.—Organized in 1858. The first class graduated in 1860. It has a faculty of 9 professors and 86 assistants, instructors, etc., a total of 95. The course covers four years of eight months each. Fees: First and second years, \$205 each; third, \$160, and \$195 for the fourth year. The Secretary is Dr. Joseph H. Raymond. Total registration, 1909-10, was 368; graduates, 72. The fifty-third session begins Oct. 1, 1910, and ends June 1, 1911.

NEW YORK HOMEOPATHIC MEDICAL COLLEGE AND HOSPITAL, Eastern Boulevard, between Sixty-third and Sixty-fourth Streets.—Organized in 1858. Incorporated in 1860 as the Homeopathic Medical College for the State of New York. The present title was assumed in 1869. The first class graduated in 1861. The Dean is Dr. Royal S. Copeland. Total registration for 1909-10 was 125; graduates, 24.

NEW YORK MEDICAL COLLEGE AND HOSPITAL FOR WOMEN, 17-19 West One Hundred and First Street.—Organized, in 1863. The first class graduated in 1864. The Dean is Dr. Helen Cooley Palmer. The total registration for 1909-10 was 24; graduates, 4.

UNIVERSITY AND BELLEVUE HOSPITAL MEDICAL COLLEGE, First Avenue and Twenty-sixth Street.—Organized in 1898 by the union of the New York University Medical College, organized in 1841, and the Bellevue Hospital Medical College, organized in 1861. It is the Medical Department of New York University. The faculty is composed of 36 professors and 130 instructors, etc., in all 166. The course covers four years of eight months each. The fees are \$200 per year. The Dean is Dr. Ezbert Le Fevre. Total registration for 1909-10 was 474; graduates, 64. The next session begins Sept. 28, 1910, and ends June 1, 1911.

Syracuse

SYRACUSE UNIVERSITY COLLEGE OF MEDICINE, 307-311 Orange Street.—Organized in 1872 as the College of Physicians and Surgeons of Syracuse University. The present title was assumed in 1875. In 1872 Geneva Medical College was merged with it. The first class was graduated in 1873. The faculty is composed of 15 professors and 45 assistant professors, lecturers and instructors, in all 60. The course covers four years of eight months each. The completion of two years in an accredited college of liberal arts is required for admission. The total fees for each of the four years, respectively, are \$181, \$191, \$151 and \$166. The Dean is Dr. John L. Heffron. The total registration for 1909-10 was 140; graduates, 27. The thirty-ninth session begins Oct. 4, 1910, and ends June 14, 1911.

NORTH CAROLINA

North Carolina, population 2,142,084, has four medical schools, one of which gives only the first two years of the medical course. The Medical Department of the University of North Carolina is located at Chapel Hill, population 1,099. The Leonard School of Medicine is at Raleigh, population 14,512. The North Carolina College is at Charlotte, population 35,101. Wake Forest School of Medicine is at Wake Forest, population 823.

Chapel Hill

UNIVERSITY OF NORTH CAROLINA MEDICAL DEPARTMENT.—Organized in 1890. Until 1902 this school gave only the work of the first two years, when the course was extended to four years by the establishment of a department at Raleigh. The first class graduated in 1903. A class was graduated each subsequent year, including 1910, when the clinical department at Raleigh was discontinued. The faculty is composed of 22 professors and 25 lecturers, assistants, etc., a total of 47. The total fees for the two years, respectively, are \$114 and \$116. The Dean is Dr. G. H. Manning. The total registration for 1909-10 was 74; graduates, 14. The twenty-fifth session begins Sept. 5, 1910, and ends May 30, 1911.

Charlotte

NORTH CAROLINA MEDICAL COLLEGE, Church and Sixth Streets.—Organized in 1887 at Davidson as the Davidson School of Medicine. It was a preparatory school only, not granting any degrees until 1893, when it was chartered under its present name. The first class was graduated in 1893. Removed to Charlotte in 1907. The faculty numbers 27. The course covers four years of eight months each. Fees: First three years, \$85 each, and \$100 for the fourth year. The Dean is Dr. Walter O. Nisbet. The total registration for 1909-10 was 107; graduates, 14. The next session begins Sept. 14, 1910, and ends May 1, 1911.

Raleigh

LEONARD MEDICAL SCHOOL.—Colored. This department of Shaw University was established in 1882. Classes were graduated in 1886, 1888 and in all subsequent years. It has a faculty of 12. The course covers four years of seven months each. The total fees for each year are \$15; graduation fee, \$10. The Dean is Dr. William Moncre. Total registration for 1909-10 was 133; graduates, 23. The twenty-ninth session begins Sept. 29, and ends May 11, 1911.

Wake Forest

WAKE FOREST COLLEGE SCHOOL OF MEDICINE.—This school was organized in 1902. The faculty numbers 10. It only gives the first two years of the medical course, which constitute a part of the course for the B.S. degree. Each annual course extends over nine months. The fees are \$100 each year. The Dean is Dr. John Brewer Powers. The total registration for 1909-10 was 37. The ninth session begins Sept. 6, 1910, and ends May 20, 1911.

NORTH DAKOTA

North Dakota, population 536,103, has one medical college, the College of Medicine of the State University of North Dakota, which is situated at University near Grand Forks, a city of 14,000 people.

University

UNIVERSITY OF NORTH DAKOTA COLLEGE OF MEDICINE.—Organized in 1905. The faculty is composed of 9 professors and 7 instructors, a total of 16. The course consists of two years' academic work and two years of medical college subjects, occupying nine months each year. The total fees for each of the medical years are \$50. The Dean is M. A. Brannon, A.M. The total registration for 1909-10 was 36. The sixth session begins Sept. 20, 1910, and ends June 15, 1911.

OHIO

Ohio, population 4,594,240, has six medical colleges. Two of these, the Ohio-Miami Medical College of the University of Cincinnati and the Eclectic Medical College, are located in Cincinnati, a city of 351,212 inhabitants. Cleveland, population 506,938, contains two medical schools: Western Reserve Medical College and the Cleveland-Pulte Medical College. Columbus, population 155,340, contains one medical college, the Starling-Ohio Medical College. Toledo, with 174,059 people, has one medical school, the Toledo Medical College.

Cincinnati

THE OHIO-MIAMI MEDICAL COLLEGE OF THE UNIVERSITY OF CINCINNATI.—Organized in 1909 by the union of the Ohio Medical College (founded in 1819) with the Miami Medical College (founded in 1852). The Ohio Medical College became the Medical Department of the University of Cincinnati, April 26, 1896. Under a similar agreement, March 2, 1909, Miami Medical College also merged into the University when the present title was taken. The faculty consists of 53 professors, 74 associates, assistants, etc., a total of 127. The course covers four years of eight months each. The fees are a tuition fee of \$125 a year; a matriculation fee of \$5, payable but once, and a graduation fee of \$25. The Secretary is Dr. E. Otis Smith. The total registration for 1909-10 was 191; graduates, 41. The next session begins Sept. 28, 1910, and ends June 3, 1911.

ECLECTIC MEDICAL COLLEGE, 630 West Sixth Street.—Organized in 1832 at Worthington as the Worthington Medical College. Removed to Cincinnati in 1843. In 1845 it was chartered as the Eclectic Medical Institute. In 1857 the American Medical College, organized in 1839, was merged into it, and in 1859 the Eclectic College of Medicine and Surgery, organized in 1856, merged into it. In 1910 it assumed its present title. Classes were graduated in 1833 and in all subsequent years except 1839 to 1843, inclusive. It has a faculty of 19 professors and 6 lecturers and assistants, a total of 25. The course covers four years of thirty weeks each. The fees are \$90 for each year. The Dean is Dr. Rolla L. Thomas, 792 East McMillan Street. Total registration for 1909-10 was 91; graduates, 20. The next session begins Sept. 20, 1910, and ends May 4, 1911.

Cleveland

CLEVELAND-PULTE MEDICAL COLLEGE, Prospect Avenue and Huron Road.—Homeopathic.—Organized in 1849 as the Western College of Homeopathic Medicine. The first class graduated in 1853. In 1857 it became the Western Homeopathic College and in 1870 it became the Homeopathic Hospital College when the Homeopathic Medical College for Women, organized in 1868, merged into it. In 1894 it became the Cleveland University of Medicine and Surgery. Toledo

TOLEDO MEDICAL COLLEGE, Cherry and Page Streets.—Organized in 1833. The first class graduated in 1833. The faculty numbers 50. The curriculum embraces four years of eight months each. The fees are \$100 for each year, with a matriculation fee of \$5, payable once. The Secretary is Dr. E. I. McKesson. The total registration for 1909-10 was 45; graduates, 9. The next session begins Oct. 3, 1910, and ends May 26, 1911.

OKLAHOMA

Oklahoma, population 1,592,401, has one medical college, the School of Medicine of the State University of Oklahoma. The work of the first and second years is given in the academic laboratories at Norman, a city of 4,000 inhabitants. The work of the third and fourth years is given in Oklahoma City, which has a population of 45,380 and which is eighteen miles north of Norman.

Norman and Oklahoma City

STATE UNIVERSITY OF OKLAHOMA SCHOOL OF MEDICINE.—Organized in 1900. Gave only the first two years of the medical course until 1910, when it absorbed the Epworth College of Medicine and established a clinical department at Oklahoma City. It has a faculty of 27 professors and 13 instructors, a total of 40. The course is four years of nine months each. An optional course of six years is offered for the degrees of B.S., and M.D. The total fees for the four years, respectively, are \$30, \$10, \$100 and \$105. The Secretary is Dr. J. D. MacLaren, Box 382, Norman. The total registration for 1909-10 was 72; graduates, 7. The eleventh session begins Sept. 14, 1910, and ends June 8, 1911.

OREGON

Oregon, population 505,339, has two medical colleges: The Medical Department of Willamette University, located at Salem, a city of 14,000 people, and the University of Oregon Medical Department, in Portland, a city of 119,007 population.

Portland

UNIVERSITY OF OREGON, MEDICAL DEPARTMENT, Lovejoy and Twenty-third Streets.—Organized in 1887. The first class graduated in 1888. It has a faculty of 15 professors and 35 lecturers, assistants, etc., a total of 50. The course is four years of thirty weeks each. Fees: First year, \$142.50; second, \$137.50; third, \$10.50, and for the fourth, \$57.50. The Dean is Dr. Simeon E. Joephi. The total registration for 1909-10 was 80; graduates, 15. The twenty-fourth session begins Sept. 12, 1910, and ends May 1, 1911.

Salem

MEDICAL DEPARTMENT WILLAMETTE UNIVERSITY.—Organized in 1865 at Salem. Classes were graduated in 1867 and in all subsequent years except 1896. It moved to Portland in 1878, but returned to Salem in 1895. The faculty numbers 20. The course is four years of eight months each. The fees for the four years, respectively, are \$122.50, \$110, \$87.50 and \$57.50. The Dean is Dr. W. H. Byrd. The total registration for 1909-10 was 35; graduates, 4. The next session begins Oct. 1, 1910, and ends June 1, 1911.

PENNSYLVANIA

Pennsylvania, population 7,241,716, has seven medical colleges. Of these Philadelphia, having a population of 1,515,756, contains six, as follows: University of Pennsylvania, Department of Medicine, Jefferson Medical College, Hahnemann Medical College, Woman's Medical College of Pennsylvania, Medico-Chirurgical College of Philadelphia and Temple University Department of Medicine. The other school, the Medical Department of the University of Pittsburg, is situated in Pittsburg, a city of 558,123 people.

Philadelphia

UNIVERSITY OF PENNSYLVANIA, DEPARTMENT OF MEDICINE, Thirty-sixth Street and Hamilton Walk.—Organized in 1765. Classes were graduated in 1768 and in all subsequent years except 1772-79, inclusive. The original title was the Department of Medicine, College of Philadelphia, which was changed to the present title in 1791. It granted the first medical diploma issued in America. The faculty is made up of 26 professors, 18 associate adjunct and assistant professors and 120 demonstrators, lecturers, associates, instructors, etc., a total of 164. The requirements for admission are the equivalent of work prescribed for the first two years in recognized colleges, which work must include a knowledge of physics, chemistry and general biology or zoology with laboratory work as specified by the College Entrance Examining Board and, in addition, two foreign languages, one of which must be French or German. The course embraces study of four years of nine months each. The total fees for each of the four years, respectively, are \$218, \$213, \$210 and \$211.50. The Dean is Dr. Allen J. Smith. Total registration for 1909-10 was 529; graduates, 134. The next session begins Sept. 23, 1910, and ends June 21, 1911.

JEFFERSON MEDICAL COLLEGE, Tenth and Walnut Streets.—Organized in 1825 as the Medical Department of Jefferson College, Cannonsburg. The first class graduated in 1826. The present title was assumed in 1838. It has a faculty of 25 professors and 115 lecturers, demonstrators, etc., a total of 140. The course of study covers graded work of four years of eight months each. An optional fifth year is offered. The tuition is \$180 a year, with a matriculation fee of \$5, paid but once. The Dean is Dr. James W. Holland. The total registration for 1909-10 was 531; graduates, 141. The eighty-sixth session begins Sept. 26, 1910, and ends June 5, 1911.

MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA, Cherry Street, between Seventeenth and Eighteenth Streets.—Organized in 1881. The first class graduated in 1882. The faculty is composed of 33 professors and 76 lecturers, assistants, etc., a total of 109. The course embraces four years of eight months each. An optional preliminary year devoted to physics, chemistry and biology is offered. Fees, \$150 per year; matriculation, \$5, payable once. The Dean is Dr. Seneca Egbert. The total registration for the college year 1909-10 was 455; graduates, 69. The thirtieth session begins Sept. 26, 1910, and ends June 3, 1911.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA. Twenty-first and N. College Avenue.—Organized in 1850. Classes were graduated in 1851 and in all subsequent years except 1861 and 1862. It has a faculty of 10 professors and 50 assistants, lecturers, etc., in all 60. The curriculum covers four years of eight months each. Fees, about

\$145 each year. The Dean is Dr. Clara Marshall. The total registration for 1909-10 was 114; graduates, 31. The 61st session begins Sept. 21, 1910, and ends May 31, 1911.

HAHNEMANN MEDICAL COLLEGE AND HOSPITAL.—Organized in 1848 as the Homeopathic Medical College of Pennsylvania. In 1869 it united with the Hahnemann Medical College of Philadelphia, taking the present title. The first class graduated in 1849. It has a faculty of 28 professors and 52 lecturers, instructors, etc., in all 80. The work covers four years of eight months each. Fees: For each year, \$150; matriculation, \$5. The Dean is Dr. William B. Van Lennep. The total registration for the college year 1909-10 was 159; graduates, 37. The 63d session begins Sept. 26, 1910, and ends June 1, 1911.

THE TEMPLE UNIVERSITY, DEPARTMENT OF MEDICINE. Eighteenth and Buttonwood Streets.—Organized in 1901. The first class graduated in 1904. The faculty numbers 84. It gives a four-year day course. The fees are \$150 per year. The Dean is Dr. Frank C. Hammond. The total registration for 1909-10 was 197; graduates, 36. The 10th session begins Sept. 15, 1910, and ends June 3, 1911.

Pittsburg

UNIVERSITY OF PITTSBURG, MEDICAL DEPARTMENT. Brereton Avenue and Thirtieth Street.—Organized in 1886 as the Western Pennsylvania Medical College. Became the Medical Department of the University of Pittsburg in 1909. The first class graduated in 1887. The faculty is composed of 43 professors and 60 associates, assistants, etc., 103 in all. The course of study embraces four years of nine months each. The total fees are \$210 each year. The Dean is Dr. Thomas S. Arbuthnot. The total registration for 1909-10 was 309; graduates, 60. The 27th session begins Oct. 5, 1910, and ends June 15, 1911.

PHILIPPINE ISLANDS

The Philippine Archipelago, having a population of 7,635,436, has two medical colleges, the University of St. Thomas, Medical Department, and the Philippine Medical School. Both are located in the City of Manila, which in 1903 had a population of 219,928.

Manila

UNIVERSITY OF ST. THOMAS, MEDICAL DEPARTMENT.—The University was founded by a papal decree in 1587, and the medical school was added in 1771. The faculty numbers 154. The course extends over a period of six years of nine months each. The first year is a preparatory one, devoted to the teaching of physics, chemistry and biology. The degree of licenciado is conferred at the conclusion of the fifth year, and the degree of doctorado at the end of the sixth year, during which only special work is done. This last year is optional, the degree of licenciado entitling the holder to all the rights and privileges of the medical practitioner. The degree is equivalent to the English M.B. The Rector of the university is Dr. Fr. Raimundo Velasquez; the Secretary of the Medical Department is Lic. Blas C. Alcuaz. The total registration for 1908-9 was 379; graduates, 151.

PHILIPPINE MEDICAL SCHOOL.—Organized in 1907 under the support of the Philippine Commission. The faculty numbers 42. The course extends over five years of thirty-five weeks each. The requirements for admission conform to the standards in the United States and Great Britain. The Secretary is Dr. Harry T. Marshall. The total registration for 1908 was 52; graduates, 8. The third session began June 7, 1909, and ended Feb. 26, 1910.

SOUTH CAROLINA

South Carolina, population 1,510,566, has one medical college, situated in Charleston, a city of 56,573 people.

Charleston

THE MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA.—Founded in 1823 as the Medical College of South Carolina. In 1832 it was chartered with the present title. Classes were graduated in 1825 and in all subsequent years except 1861 to 1865 inclusive. It has a faculty of 11 professors and 22 lecturers, instructors, etc., a total of 33. Total enrolment for 1909-10 was 229; graduates, 38. The 88th session begins Oct. 1, 1910, and ends May 31, 1911.

SOUTH DAKOTA

South Dakota, population 498,077, has one medical college, the University of South Dakota, College of Medicine, located at Vermillion, a city of 2,183 people.

Vermillion

UNIVERSITY OF SOUTH DAKOTA, COLLEGE OF MEDICINE.—Organized in 1907. Offers only the first two years of the medical course. Two years work in a college of liberal arts is required for admission. The faculty numbers 9. The Dean is Christian P. Lommen. B.S. The total registration for 1909-10 was 7. The 4th session begins Sept. 12, 1910, and ends June 8, 1911.

TENNESSEE

Tennessee, population 2,248,404, has eight medical colleges. Of these Vanderbilt University Medical Department, the Medical Department of the Universities of Nashville and Tennessee and Meharry Medical College are situated in Nashville, a city

with a population of 106,476. Knoxville, population 37,738, contains two colleges, Tennessee Medical College and Knoxville Medical College. Memphis Hospital Medical College, the College of Physicians and Surgeons and the University of West Tennessee are located in Memphis, population 136,363.

Knoxville

TENNESSEE MEDICAL COLLEGE, MEDICAL DEPARTMENT OF LINCOLN MEMORIAL UNIVERSITY. Cleveland Street and Dameron Avenue.—Organized in 1889. The first class graduated in 1890. It has a faculty of 20 professors and 7 assistants, a total of 27. The curriculum covers four years of seven months each. Fees: First and second years, \$50; third and fourth years, \$60; matriculation fee, \$5; graduation fee, \$25. The total registration for 1909-10 was 98; graduates, 20. The 21st session begins Oct. 1, 1910, and ends May 3, 1911.

KNOXVILLE MEDICAL COLLEGE. Colored. Clinton and McGhee Streets. Organized in 1900. Classes were graduated in 1900 and in all subsequent years except 1906 and 1907. The Secretary is Dr. H. M. Green, Famous Building. There were 21 students and 1 graduate for the session of 1909-10.

Memphis

COLLEGE OF PHYSICIANS AND SURGEONS. Opposite City Hospital. Organized in 1906. The first class graduated in 1907. It has a faculty of 42. The course covers four years of seven and a half months each. The Dean is Dr. E. C. Ellett. The total registration for 1909-10 was 105; graduates, 17. The fifth session begins Sept. 15, 1910, and ends May 1, 1911.

MEMPHIS HOSPITAL MEDICAL COLLEGE. Marshall Avenue and Myrtle Street.—Organized in 1880. The first class graduated in 1881. It has a faculty of 12 professors and 26 lecturers, instructors, etc., a total of 38. The course covers four years of thirty weeks each. The total fees for each of the first three years are \$100; for the fourth, \$125. The Dean is Dr. W. B. Rogers. Total registration for 1909-10 was 425; graduates, 101. The 31st annual session will begin Oct. 1, 1910, and close May 18, 1911.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF WEST TENNESSEE. Colored, 1190 South Phillips Place.—Organized in 1900. The first class graduated in 1904 and a class graduates each subsequent year. It has a faculty of 16. The course is four years of seven months each. The fees are \$50 per year; graduation \$10 extra. The Dean is Dr. M. V. Lynk. Registration for 1909-10 was 35; graduates, 6. The 11th session begins Sept. 14, 1910, and ends April 14, 1911.

Nashville

VANDERBILT UNIVERSITY, MEDICAL DEPARTMENT. Elm Street and Fifth Avenue.—This school was founded in 1874. The first class graduated in 1875. The faculty consists of 23 professors and 24 lecturers, a total of 47. The course covers four years of seven and a half months each. The total fees for each of the first three years are \$125, and for the fourth year, \$150. The Dean is Dr. William L. Dudley. The total registration for 1909-10 was 271; graduates, 39. The 37th session begins Sept. 15, 1910, and ends May 1, 1911.

UNIVERSITIES OF NASHVILLE AND TENNESSEE, MEDICAL DEPARTMENT.—Organized in 1909 by the union of the University of Nashville, Medical Department (founded in 1850), with the University of Tennessee, Department of Medicine (founded in 1876). The college has a faculty of 51. The course covers four years of thirty-two weeks each. The total fees are \$125 for each of the first three years and \$150 for the fourth year. The Dean is Dr. R. O. Tucker. The total registration for 1909-10 was 203; graduates, 65. The next session begins Sept. 5, 1910, and ends May 1, 1911.

MEHARRY MEDICAL COLLEGE, Colored. Maple and Chestnut Streets.—This school was organized in 1876 and is the Medical Department of Walden University. The faculty is made up of 12 professors and 14 instructors, demonstrators, etc., 26 in all. The work embraces four years of thirty-two weeks each. The total fees for each of the four years respectively are \$56, \$59, \$57 and \$65. The Dean is Dr. G. W. Hubbard. Total registration for 1909-10 was 281; graduates, 56. The 35th session begins Sept. 14, 1910, and ends April 25, 1911.

TEXAS

Texas, population 3,780,574, has four medical colleges. The University of Texas Department of Medicine is located at Galveston, a city of 38,000 inhabitants. The Medical Department of Fort Worth University is at Fort Worth, population 68,132. The Baylor University College of Medicine and the Medical Department of Southwestern University are situated in Dallas, population 104,341.

Dallas

BAYLOR UNIVERSITY COLLEGE OF MEDICINE, 435-37 South Ervay Street.—Organized in 1900 as the University of Dallas, Medical Department. In 1903 it took its present name and became the Medical Department of Baylor University at Waco. It acquired the charter of Dallas Medical College in 1904. The first class graduated in 1901. The faculty numbers 28. The course is four years of seven months each. The fees are \$100 each year; matriculation fee of \$5, paid but once; graduation fee, \$25. The Dean is Dr. E. H. Cary. Total registration for 1909-10 was 67; graduates, 9. The 11th session begins Oct. 3, 1910, and ends May 1, 1911.

SOUTHWESTERN UNIVERSITY MEDICAL COLLEGE.—Organized in 1903. The first class graduated in 1904. It has a faculty of 19 professors and 14 instructors, assistants, etc. The course of instruction covers four years of seven months each. The fees for the four years respectively are \$110, \$105, \$100 and \$125. The Dean is Dr. John O. McReynolds. Total registration for 1909-10 was 61; graduates, 17. The 8th session begins Sept. 29, 1910, and ends April 30, 1911.

Fort Worth

MEDICAL DEPARTMENT OF FORT WORTH UNIVERSITY. Calhoun and Fifth Streets.—Organized in 1894. The first class graduated in 1895. It has a faculty of 16 professors and 22 lecturers, assistants, etc., in all 38. The course covers four years of seven months each. The total fees for each of the first three years are \$105, and \$130 for the fourth year. The Dean is Dr. W. R. Thompson. The total registration for the college year 1909-10 was 81; graduates, 28. The 17th session begins Sept. 27, 1910, and ends May 13, 1911.

Galveston

UNIVERSITY OF TEXAS, DEPARTMENT OF MEDICINE. Avenue B and Ninth Street.—Organized in 1891. The first class graduated in 1892. It has a faculty of 9 professors and 14 lecturers. The curriculum embraces four years of eight months each. The entrance requires one year of collegiate work in addition to a four-year high school education. The total fees for the four years respectively are \$55, \$30, \$20 and \$5. The Dean is Dr. William S. Carter. Total registration for 1909-10 was 206; graduates, 35. The 20th session begins Oct. 1, 1910, and ends May 31, 1911.

UTAH

Utah, population 336,122, has one medical college, the Medical Department of the University of Utah, situated at Salt Lake City, which has 64,538 people.

Salt Lake City

UNIVERSITY OF UTAH, DEPARTMENT OF MEDICINE.—Organized in 1906. Gives only the first two years of the medical course. Each course covers thirty-six weeks. Two years of collegiate work are required for admission. The medical faculty consists of 6 professors and 10 lecturers and assistants, a total of 16. The fees are \$65 each year. The Acting-dean is Dr. George M. Marshall. Total registration for 1909-10 was 30. The 4th session begins Sept. 19, 1910, and ends June 3, 1911.

VERMONT

Vermont, population 353,739, has one medical school, located at Burlington, a town of 21,880 people.

Burlington

UNIVERSITY OF VERMONT COLLEGE OF MEDICINE. Pearl Street, College Park.—Organized with complete course in 1822. Classes graduated in 1823 to 1836, inclusive, when the school was suspended. It was reorganized in 1853 and classes were graduated in 1854 and in all subsequent years. The faculty numbers 54. The course of study covers four years of seven months each. The total fees for each of the first three years are \$135, and \$165 for the fourth year. The Secretary is Dr. James N. Jenne. The total registration for 1909-10 was 178; graduates, 30. The next session begins Nov. 14, 1910, and ends June 20, 1911.

VIRGINIA

Virginia, population 2,032,567, has three medical colleges, one, the Medical Department of the University of Virginia, situated in Charlottesville, population 6,449, and two, the Medical College of Virginia and the University College of Medicine, in Richmond, population 109,461.

Charlottesville

UNIVERSITY OF VIRGINIA, DEPARTMENT OF MEDICINE.—Organized in 1827. Classes were graduated in 1828 and in all subsequent years except 1865. It has a faculty of 15 professors and 15 lecturers, instructors, assistants, etc., a total of 30. The requirements for admission are the completion of a four years' high school course, or its equivalent, and a year of college work devoted to chemistry, physics and biology. Fees: First year, \$150; second year, \$140; third year, \$120; fourth year, \$100. The Dean is Dr. R. H. Whitehead. The total registration for 1909-10 was 87; graduates, 31. The next session begins Sept. 15, 1910, and ends June 14, 1911.

Richmond

MEDICAL COLLEGE OF VIRGINIA. Marshall and College Streets.—Organized in 1838 as the Medical Department of Hampden Sydney College. Present title was taken in 1854. Classes were graduated in 1840 and in all subsequent years. It has a faculty of 16 professors and 38 lecturers, instructors, etc., a total of 54. The requirement for admission is a full four-year high school education. The course embraces four years of eight months each. Fees, \$100 each year; graduation fee, \$30. The Dean is Dr. Christopher Tompkins. The total registration for the college year 1909-10 was 191; graduates, 38. The 73d session begins Sept. 13, 1910, and ends May 30, 1911.

UNIVERSITY COLLEGE OF MEDICINE. Eleventh and Clay Streets.—Organized in 1893. The first class graduated in 1894. It has a faculty of 66. Curriculum covers four years of eight months each. The total fees are \$100 for each year. The Dean is Dr. A. L. Gray. The total registration for the college year 1909-10 was 137; graduates, 22. The 18th session begins Sept. 14, 1910, and ends May 25, 1911.

WEST VIRGINIA

West Virginia, population 1,135,206, has one medical college, College of Medicine of the West Virginia University, located at Morgantown, a city of 3,900 inhabitants.

Morgantown

WEST VIRGINIA UNIVERSITY COLLEGE OF MEDICINE.—Organized in 1902. Gives only the first two years of the medical course. Each college term extends over nine months. The faculty consists of 8 professors and 5 assistants, 13 in all. Tuition to students residing in the state, \$25; for others, \$50 per year. The Dean is Dr. J. N. Simpson. The total registration for the college year 1909-10 was 27. The 9th session begins Sept. 15, 1910, and ends June 15, 1911.

WISCONSIN

Wisconsin, population 2,356,874, has three medical colleges, the Medical Department of the University of Wisconsin, which teaches the first two years of the medical course, and is located at Madison, a city having a population of 27,610, and the Milwaukee Medical College and Wisconsin College of Physicians and Surgeons, situated in Milwaukee, a city of 332,495 people.

Madison

UNIVERSITY OF WISCONSIN COLLEGE OF MEDICINE.—Organized in 1907. Gives only the first two years of the medical course. The 3d session begins Sept. 29, 1910, and ends June 23, 1911.

Milwaukee

MILWAUKEE MEDICAL COLLEGE. MEDICAL DEPARTMENT OF MARQUETTE UNIVERSITY. Ninth and Wells Streets.—Organized in 1894. The first class graduated in 1895. It became the Medical Department of the Marquette University in 1907. It has a faculty of 30 professors and 36 lecturers, instructors, etc., a total of 66. The course covers four years of eight months each. The total fees are \$135 each for the first three years and \$150 for the fourth year. The Dean is Dr. Warren B. Hill. The total registration for 1909-10 was 293; graduates 47. The 17th session begins Oct. 4, 1910, and ends May 22, 1911.

WISCONSIN COLLEGE OF PHYSICIANS AND SURGEONS. Fourth Street and Reservoir Avenue.—Organized in 1893. The first class graduated in 1894. In 1908 it became the medical department of Carroll College. It has a faculty of 30 professors and 26 lecturers, instructors, etc., a total of 56. The curriculum includes four years of eight months each. Fees: Matriculation, paid once, \$5; general ticket, \$125. The Dean is Dr. Thomas C. Phillips. The total registration for 1909-10 was 51; graduates, 6. The 19th session begins Oct. 3, 1910, and ends May 30, 1911.

CANADA

Manitoba

MANITOBA MEDICAL COLLEGE. Winnipeg.—It is the Medical Faculty of the University of Manitoba. Organized in 1883, first class graduated in 1886 and a class graduated each subsequent year. The faculty numbers 49. The fees are \$155 for the first year and \$150 for each subsequent year. The entire course covers five years. The Dean is Dr. H. H. Chown, 263 Broadway, Winnipeg. Total registration for 1909-10 was 110; graduates, 3. The next session begins Sept. 26, 1910, and ends May 1, 1911.

Nova Scotia

HALIFAX MEDICAL COLLEGE. Medical Faculty of Dalhousie University, Halifax.—Organized 1867 as Halifax School of Medicine, united same year with Dalhousie University, separately incorporated 1876, affiliated with Dalhousie University 1885, first class graduated 1872 and a class graduated each subsequent year except 1873 and 1886. The Medical Faculty of Dalhousie University is the Examining Board for Nova Scotia and teaches only the premedical branches; Halifax Medical College teaches the medical courses, but the Medical Faculty conducts the examinations and grants the degrees. The course covers four years. The Dean is Dr. George L. Sinclair; the Secretary is Dr. A. W. H. Lindsay. The total registration for 1909-10 was 69; graduates, 9. The next session begins Aug. 25, 1910, and ends April 27, 1911.

Ontario

UNIVERSITY OF TORONTO. FACULTY OF MEDICINE, Toronto.—Organized 1843 as the Medical Faculty of King's College. Abolished in 1853. Re-established in 1887. The course of study covers five years of eight months each. In 1903 it absorbed Trinity Medical College. The Secretary is Dr. A. Primrose. The total registration for 1909-10 was 590; graduates, 125. The next session begins Sept. 27, 1910, and ends May 18, 1911.

MEDICAL FACULTY OF QUEEN'S UNIVERSITY, Kingston.—Organized 1854, first class graduated in 1855, and a class graduated each subsequent year. The faculty was originally a department of the University, but a separation took place in 1866, when the school was conducted under the charter of the Royal College of Physicians and Surgeons at Kingston. In 1892 the school again became an integral part of Queen's University. The fees amount to \$100 each year; fee for M.D., C.M. degrees, \$30. The course covers five years of seven months each. The total registration in 1909-10 was 228; graduates, 30. The Dean is Dr. A. R. B. Williamson. The next session begins Sept. 28, 1910, and ends April 26, 1911.

MEDICAL DEPARTMENT OF WESTERN UNIVERSITY, London.—Organized in 1881, first class graduated in 1883 and a class graduated each year subsequently. The faculty numbers 22. The course is

five years of seven and a half months each. The Registrar is Dr. W. E. Waugh. Total registration for 1909-10 was 116; graduates, 20. The next session begins Sept. 15, 1910, and ends May 1, 1911.

Quebec

MEDICAL FACULTY OF MCGILL UNIVERSITY.—Founded 1824 as Montreal Medical Institution; became the Medical Faculty of McGill University in 1829; first class graduated under the university auspices in 1833. No session between 1836-39 owing to political troubles. In 1905 it absorbed the Faculty of Medicine of the University of Bishop College. The course extends over five years of eight months each. The faculty numbers 101. The total fees for each of the five years respectively are \$138, \$138, \$148, \$154 and \$184. The total registration for 1909-10 was 329; graduates, 79. The Registrar is Dr. John W. Scane. The next session begins Oct. 3, 1910, and ends May 20, 1911.

LAVAL UNIVERSITY, MEDICAL DEPARTMENT, Quebec and Montreal.—The Quebec School of Medicine, organized in 1848, became in 1852 Medical Department of Laval University; first class graduated in 1855, and a class graduated each subsequent year. Department organized in Montreal in 1878. The course extends over five years. The Deans are Dr. Michael Joseph Ahern, Quebec, and Dr. E. P. Lachapelle, Montreal. Total registration at the two departments, 1909-10 was 311; graduates, 42. The next session at Quebec begins Sept. 15, 1910, and ends June 20, 1911; at Montreal the next session begins Oct. 3, 1910, and ends June 20, 1911.

TURKEY

Constantinople.—University of Constantinople.
(Another medical department of this university is located at Damascus).

URUGUAY

Montevideo.—Universidad.

WALES

Cardiff.—University of Wales (Cardiff School of Medicine).

EDUCATIONAL STANDARDS ABROAD

The educational standards in foreign countries regarding which definite information has been obtained are briefly stated as follows:

ARGENTINE REPUBLIC.—Elementary education extends between the ages of 6 and 14, and secondary education between the ages of 12 and 18, thereby overlapping the elementary by two years. Twelve years of study, therefore, lead to the medical course, which covers six years, including preliminary work in physics, chemistry and biology. The complete course requires 18 years and the minimum age at completion of the course is 24.

AUSTRIA.—Elementary education extends between the ages of 6 and 14, overlapping the gymnasium course by four years, the latter extending between the ages of 10 and 18. Twelve years of study, therefore, admit to medicine. The medical course covers six years and includes preliminary courses in physics, chemistry and biology. The total time required is 18 years and the minimum age at completion is 24.

BELGIUM.—Elementary education extends between the ages of 6 and 14, overlapping the work in the Royal Athénées, the secondary schools, by three years, the latter extending between the ages of 11 and 18. The time spent in the primary and secondary schools is, therefore, 12 years. An additional year devoted to physics, chemistry and biology in a college of science admits to the five-year medical course. The time necessary to complete the work is 18 years and the minimum age at completion is 24.

BOLIVIA.—Elementary education extends between the ages of 6 and 14, and secondary education between the ages of 12 and 18, thereby overlapping the elementary by two years. Twelve years of study, therefore, lead to the medical course, which covers six years, including preliminary work in physics, chemistry and biology. The complete course requires 18 years and the minimum age at the completion of the course is 24.

BRAZIL.—Elementary education extends between the ages of 7 and 15, overlapping the work of the gymnasium by three years, the latter extending between the ages of 12 and 19. Elementary work may be begun at the age of 6 years, and in such cases students may finish the gymnasium at 18. Twelve years of work lead to medicine, where six years of work are required, including preliminary courses in physics, chemistry and biology. The time required to complete the entire course is 18 years and the usual age at completion is 25.

CHILE.—Elementary education extends between the ages of 6 and 14 years, leading to the secondary, which extends from the 14th to the 18th year. A six-year medical course follows, which includes preliminary work in physics, chemistry and biology. The time to complete the entire work is 18 years and the minimum age at completion is 24.

COLOMBIA.—Elementary education extends between the ages of 6 and 14, and secondary education between the ages of 12 and 18, thereby overlapping the elementary by two years. Twelve years of study, therefore, lead to the medical course, which covers six years, including preliminary work in physics, chemistry and biology. The complete course requires at least 18 years and the minimum age at the completion of the course is 24.

DENMARK.—Elementary education extends between the ages of 6 and 12, leading to the "laerdeskoler," the secondary schools, which extend between the ages of 12 and 18, a total of 12 years. The medical course covers six years, including preliminary courses in the natural sciences. Time to complete the work is 18 years and the minimum age at completion is 24.

FRANCE.—Elementary education extends between the ages of 6 and 13 or 14. The majority of students entering the second-

ary schools, however, obtain their elementary work from tutors or in special preparatory courses connected with the lycées. The secondary school, the lycée, has a nine-year course divided into two cycles of five and four years, respectively, and extends between the ages of 11 and 18. From age 6, therefore, twelve years of training are required to complete the primary and secondary work. An additional year devoted to the natural sciences, which must be taken in a college of science, admits to the four-year medical course. Entire course, therefore, is 17 years, and the age at completion is 23.

GERMANY.—Elementary study extends between the ages of 6 and 14, overlapping the gymnasium by four years, the latter extending between the ages of 10 and 18. Then follows a six-year course, which includes preliminary courses in the natural sciences, and the last year must be spent in hospital work. This gives the right to practice, but additional work is required, and a severe examination, the "examen rigorosum," must be passed to secure the degree of doctor. Eighteen years of work lead to medical practice or 19 to the Doctorate and the age at completion is at least 24 or 25.

GREAT BRITAIN.—There appears to be no connection between elementary and secondary systems of education. Elementary public schools have been provided, extending between the ages of 6 and 12 or 15. Those entering secondary schools usually obtain their elementary instruction from private tutors or in the preparatory courses of the secondary schools. At present there are no public secondary schools in Great Britain, although that country abounds in private secondary schools, having courses varying as to age. Taking Rugby as an example, the course extends from the age of 10 to 17. Others extend from the age of 12 to 19. There are various ages at which the student may enter the medical schools, the minimum age fixed by the General Medical Council being 16. The time spent in elementary and secondary education, therefore, ranges from 10 to 13 years. Work must then be taken in physics, chemistry and biology either in a college of science or in the medical college as a part of the regular five-year medical course. Authorities agree that only a small proportion of students enter the medical school before the 18th year and few graduate in medicine before the age of 23. Since the promotion from one grade to another depends entirely on the passing of an examination, the time to complete the medical course usually requires six or more years.

GREECE.—Elementary education is given in the "demotic" schools between the ages of 6 and 10 and in the "hellenic" schools between the ages of 10 and 14, leading to the secondary schools or gymnasia, which occupy the time between the ages of 14 and 18. Twelve years are occupied, therefore, by elementary and secondary education. Two years of work in the university devoted to botany, chemistry, physics, mineralogy, geology and zoology must be completed in order to begin the four-year medical course for the degree of Doctor. To secure the right to practice, nine months of postgraduate work in a hospital must be completed. The total time requirement is 19 years and the minimum age at completion of the entire course is 25.

HUNGARY.—Elementary education extends between the ages of 6 and 12 years, overlapping secondary education, which extends between the ages of 10 and 18. The 12 years' work thus completed leads to the five-year medical course, which includes preliminary work in physics, chemistry and biology. The time for the entire course is, therefore, 17 years, and the minimum age at completion is 23.

ITALY.—Elementary education is divided into lower elementary, extending between the ages of 6 and 9 years, and higher elementary, extending between 9 and 12 years. Secondary education is given in the ginnasio, extending between the ages of 10 and 15 years, and in the liceo, which extends between the ages of 15 and 18 years. This is followed by a six-year course in medicine, which includes work in the natural sciences. The complete course, therefore, is elementary study 4 years, ginnasio 5 years, liceo 3 years and medicine 6 years, a total of 18 years. The minimum age at completion of the course is 24 years.

JAPAN.—Ordinary elementary education extends between the ages of 6 and 10 years and higher elementary education is between the ages of 10 and 14 years, overlapping the work of the "middle school" by two years, the latter extending between the ages of 12 and 17 years. Completing the work of the middle school admits to the four-year medical course in all medical schools, except those at Tokio, Kioto and Fukuoka, which require also the completion of three years of higher preliminary education.

NETHERLANDS.—Elementary education extends between the ages of 6 and 12 years, leading to the gymnasium, which extends from the 12th to the 18th year. Admission is then secured to the six-year medical course, which includes work in the natural sciences. The time to complete the entire course is 18 years and the minimum age is 24.

NORWAY.—Elementary education extends between the ages of 6 and 12 years, overlapping the secondary, which extends between the ages of 9 and 18 years. Secondary education is divided into a six-year middle school and a three-year gymnasium. The completion of the course of the gymnasium admits to the six-year medical course, which includes work in physics, chemistry and biology. The entire time, therefore, is 18 years and the minimum age at completion is 24. This gives the right to practice with the title of physician. The degree of Doctor requires extra work and the passing of special examinations.

PERU.—Elementary education extends between the ages of 6 and 14, and secondary education between the ages of 12 and 18, thereby overlapping the elementary by two years. Twelve years of study, therefore, lead to the medical course, which covers six years, including preliminary work in physics, chemistry and biology. The complete course requires 18 years and the minimum age at the completion of the course is 24.

PORTUGAL.—Elementary education extends between the ages of 6 and 12 years, thus overlapping the work of the lyceum, which extends between the ages of 9 and 16. This is followed by a course of one or two years in a faculty of philosophy and mathematics and then five years in medicine for the degree of licentiate in medicine and a sixth year for the degree of Doctor. The time for the entire course, therefore, is 18 years and the minimum age at completion is 24.

RUSSIA.—Elementary education extends for 3 years between the ages of 7 and 10. Secondary education, as given in the gymnasium, extends over 8 years between the ages of 11 and 19. Completion of the secondary work admits to the five-year medical course, which includes preliminary work in the natural sciences extending through the first two years along with other subjects. The total time is 16 years and the minimum age at completion is 24.

SPAIN.—Elementary education extends between the ages of 6 and 14 years, overlapping the work of the gymnasium, the secondary schools, which conduct work between the ages of 10 and 17. After completing the work of the gymnasium one year of "preliminary study" must be taken, devoted to chemistry and natural science. Six years more gives the degree of licentiate in medicine and one more that of doctor. The complete course, therefore, requires 18 years of study and the minimum age at completion is 24.

SWEDEN.—Elementary education extends over 7 years between the ages of 6 and 13. Secondary education consists of a five-year lower modern course and a four-year higher gymnasium, the two courses being attended by students between the ages of 9 and 18. After completing the gymnasium one year of preliminary work in the natural sciences must be taken in a college of philosophy. Seven years more of study gives the degree of licentiate in medicine, which carries with it the right to practice. To secure the degree of Doctor requires more work and the passing of special examinations. Promotion to each succeeding grade depends on the passing of an examination, and the medical course often extends to 9 or more years. The entire course, therefore, includes: elementary work, 3 years; lower modern school, 5 years; higher gymnasium, 4 years; college of philosophy, 1 year, and medicine, 7 years, a total of 20 years. The age at completion is 26 to 28 years.

SWITZERLAND.—The Cantons differ somewhat in the length of their secondary courses, but all agree in regard to the preliminary work for admission to medicine and the length of the medical course. Taking the Canton of Zürich as an example, the elementary work extends over 6 years between the ages of 6 and 12. The secondary schools, known as gymnasia (real-schulen or lycea), have courses covering seven years, students attending between the ages of 11 and 18. Graduation from the gymnasium admits to the five-year medical course, which includes preliminary courses in physics, chemistry and biology. The entire course, therefore, requires: elementary work, 5 years; gymnasium, 7 years, and medicine, 5 years, a total of 17 years. The minimum age at completion is 23. The degree of Doctor is not essential to practice, but may be obtained by writing special thesis and taking certain courses without necessarily requiring a longer course.

TURKEY.—Elementary education extends from the age of 6 to 10 years inclusive, intermediate education from 10 to 14, secondary education from 14 to 17 years and the medical education from 17 to 23. The total number of years, therefore, is 17 years and the minimum age at completion is 23. The sixth year of the medical course must be spent in a hospital.

URUGUAY.—Elementary education extends between the ages of 6 and 14 years, leading to the secondary, which extends from the 14th to the 18th year. A six-year medical course follows, which includes preliminary work in physics, chemistry and biology. The time to complete the entire work is 18 years and the minimum age at completion is 24.

Total medical colleges in all foreign countries..... 185
Total in the United States alone..... 133

Counting also the 20 sectarian schools, the graduates of which treat diseases, gives the United States a total of 153.

MEDICAL STANDARDS ABROAD COMPARED

The list of foreign medical colleges, on pages 676 to 678, shows a total of 185 such colleges outside the United States, while this country alone has 133. All European medical schools are medical faculties of universities or are under the direct control of universities, and there are no proprietary schools such as predominate in this country.

The information given regarding preliminary education as well as collegiate and medical was obtained from original sources and from foreign publications and has been verified in most instances by the American consuls in the different countries.

The requirements in twenty foreign countries are graphically presented in the accompanying chart, where each division of education is shown according to the ages at which students are in attendance. The shaded portions of the bands represent primary and secondary education, the black portions the medical, and the white portions represent the requirements of higher preliminary education, including work in physics, chemistry and biology. The chart allows valuable comparisons to be

H., Homeopathic; E., Eclectic; Ph.M., Physiochemical; P. Panpathic. * Night schools. † Gives only two years of the medical course. ‡ Total fees for the fifth year are \$110.

REFERENCES TO TABLE 1

- (a) Cooper Medical College will continue to teach and will graduate those matriculated prior to 1909. After that date all work will be under the charge of the Leland Stanford Junior University Department of Medicine.
 (b) These colleges will complete their merger Jan. 1, 1911.
 (c) These colleges have been merged, retaining the name of Bennett Medical College.
 (d) Population figures given for both Kansas Cities.
 (e) This college has been suspended.

- (f) Formerly the Western Eclectic College of Medicine and Surgery of Kansas City, Kan.
 (g) This has just been reorganized on a non-sectarian basis.
 (h) Population figures include St. Paul and Minneapolis.
 (i) Tuition fees are less for residents of the state.
 (j) Merged with Western Reserve University.
 (k) These colleges have been merged with the new title, Cleveland-Pulite Medical College.
 (l) Following the suspension of the Epworth College of Medicine, this school has organized a clinical department at Oklahoma City.

- (m) Gives a five year course.
 (n) The enrollment of students given is for 1908-9; the graduates, those of 1910.
 (o) This college had 226 "matriculants and applicants" in 1908-9 according to its printed announcement. From other sources it is learned that only about 80 medical students actually attended throughout the session of 1909-10.
 (p) Hamline University still grants degrees to students matriculated prior to the fall of 1909 who could not meet the entrance requirements of the College of Medicine of the University of Minnesota, with which it was merged.

(Continued from page 681)

1. A strict enforcement of all standards and requirements, the college itself to be held responsible for any instances where they are not enforced.

2. A requirement for admission of at least a four-year high school education superimposed on eight years of grammar school work, or the actual equivalent education, this to consist of 14 units as defined by the College Entrance Examining Board and required by the Carnegie Foundation for the Advancement of Teaching (see schedule, page 681).

3. As soon as conditions warrant, the minimum requirement for admission should be enlarged to include at least one year's college work in physics, chemistry and biology and a reading knowledge of at least one modern language, preferably German or French.

4. A requirement that students be in actual attendance in the college within the first week of each annual session and thereafter.

5. That actual attendance at classes be insisted on except for good cause, such as for sickness, and that no credit be given under any circumstances for less than 80 per cent. of attendance on each course.

6. That advanced standing be granted only to students of other acceptable colleges and that in granting advanced standing there shall be no discrimination against the college's full-course student.

7. Careful and intelligent supervision of the entire school by a dean or other executive officer who holds, and has sufficient authority to carry out, fair ideals of medical education as interpreted by modern demands.

8. A good system of records showing conveniently the credentials, attendance, grades and accounts of the students.

9. A fully graded course covering four years of at least 30 weeks each, exclusive of holidays, and at least 30 hours per week of actual work; this course should be clearly set forth in a carefully prepared and printed schedule of lectures and classes.

10. Two years of work consisting largely of laboratory work in thoroughly equipped laboratories in anatomy, histology, embryology, physiology, chemistry (inorganic, organic and physiologic), bacteriology, pathology, pharmacology, therapeutics and clinical diagnosis.

11. Two years of clinical work largely in hospitals and dispensaries, with thorough courses in internal medicine (including physical diagnosis, pediatrics, nervous and mental diseases), surgery (including surgical anatomy and operative surgery on the cadaver), obstetrics, gynecology, laryngology, rhinology, ophthalmology, otology, dermatology, hygiene and medical jurisprudence.

12. At least six expert, thoroughly trained instructors in the laboratory branches, salaried so they may devote their entire time to instruction and to that research without which they cannot well keep up with the rapid progress being made in their subjects. These instructors should rank sufficiently high to have some voice in the conduct of the college. There should also be a sufficient number of assistants in each department to look after the less important details.

13. The medical teaching should be of at least the same degree of excellence as obtains in our recognized liberal arts colleges and technical schools.

14. The members of the faculty, with a few allowable exceptions, should be graduates of institutions recognized as medical colleges and should have had a training in all departments of medicine. They should be appointed because of their ability as teachers and not because they happen to be on the attending staff of some hospital or for other like reasons.

15. The college should own or entirely control a hospital in order that students may come into close and extended contact with patients under the supervision of the attending staff. The hospital should have a sufficiently large number of patients to permit the student to see and study the common variety of surgical and medical cases as well as a fair number in each of the so-called specialties.

16. The college should have easily accessible hospital facilities of not less than 200 patients which can be utilized for clinical teaching (for senior classes of 100 students or less),

these patients to represent in fair proportion all departments of medicine.

17. The college should have additional hospital facilities for children's diseases, contagious diseases and nervous and mental diseases.

18. Facilities for at least five maternity cases for each senior student, who should have actual charge of these cases under the supervision of the attending physician.

19. Facilities for at least 30 autopsies during each college session (for senior classes of 100 students or less).

20. A dispensary, or out-patient department, under the control of the college, the attendance to be a daily average of 60 cases (for senior classes of 100 students or less), the patients to be carefully classified, good histories and records of the patients to be kept and the material to be well used.

21. The college should have a working medical library to include the more modern text and reference books and 10 or more leading medical periodicals; the library room to be easily accessible to students during all or the greater part of the day; to have suitable tables and chairs and to have an attendant in charge.

22. A working medical museum having its various anatomic, embryologic, pathologic and other specimens carefully prepared, labeled and indexed so that any specimen may be easily found and employed for teaching purposes.

23. A supply of such useful auxiliary apparatus as a stereopticon, a reflectoscope, carefully prepared charts, embryologic or other models, manikins, dummies for use in bandaging, a Roentgen ray or other apparatus now so generally used in medical teaching.

24. The colleges should show evidences of reasonably modern methods in all departments and evidences that the equipment and facilities are being intelligently used in the training of medical students.

25. A clear statement of the college's requirements for admission, tuition, time of attendance on the classes, sessions and graduation should be clearly set forth, together with complete lists of its matriculants and latest graduating class in regular annual catalogues or announcements.

Definitions of a Medical College* and a Medical School†

"An institution to be ranked as a medical college must have at least six (6) professors giving their entire time to medical work, a graded course of four full years of college grade in medicine, and must require for admission not less than the usual four years of academic or high-school preparation, or its equivalent, in addition to the preacademic or grammar school studies."

By a medical school as differentiated from a medical college is meant a part of a university requiring for admission the equivalent of two years of collegiate work and which offers instruction of not less than two years' duration, leading to the degree of Doctor of Medicine.

* This definition of a college is based on that given in the revised ordinances of the State of New York and which was also adopted by the Carnegie Foundation for the Advancement of Teaching as their standard.

† Based on the definition of the term "school" adopted in 1909 by the Association of American Universities.

THE ASSOCIATION OF AMERICAN MEDICAL COLLEGES

The requirements for admission to and graduation from colleges holding membership are as follows:

Preliminary Education: (a) A bachelor's degree from an approved college or university. (b) A diploma from an accredited high school, normal school or academy requiring for admission evidence of the completion of an eight-year course in primary and intermediate grades, and for graduation not less than four years of study embracing not less than two years (4 points) of Latin or four years of either high school French or German, provided an examination is passed in the elements of Latin grammar, two years (4 points) of mathematics, two years (4 points) of English, one year (2 points) of history, one year (2 points) of physics, and six years (12 points) of further credit in language literature, history or science. (c) An examination in the following branches totaling 30 points: A. Required (16 points): Mathematics (4 points), English (4 points), History (2 points), Latin (4 points), Physics (2 points).

B. Elective (14 points): English language and literature, 4 points; language, German, French, Spanish or Greek, in each not

less than 2 points; solid geometry and trigonometry ($\frac{1}{2}$ year each), 2 points; biology (one year) or botany and zoology ($\frac{1}{2}$ year each), 2 points; chemistry (1 year), 2 points; physical geography and geology ($\frac{1}{2}$ year each), 1 point; physiology and hygiene ($\frac{1}{2}$ year each), 1 point; astronomy ($\frac{1}{2}$ year), 1 point; drawing ($\frac{1}{2}$ year), 1 point. One point in any subject in a high school or academic course demands not less than five periods per week of forty-five minutes each for eighteen weeks. (d) Certificates from reputable instructors recognized by any state board of medical examiners duly authorized by law or by the superintendents of public instruction in states having no board of examination, may be accepted in lieu of any part of this examination. (e) This examination must be conducted by or under the authority of the board of examiners or of the superintendent of public instruction of the city or state in which the college is located as provided for in subsection (d). In no case shall it be conducted by any person connected with the faculty, medical or otherwise, of the institution to which the student is seeking admission.

A student may be allowed to enter on his medical work conditioned in not more than six points, and these conditions must be removed by satisfactory examination before he is allowed to enter on the second year of his medical course.

Advanced Standing: Colleges in membership in this Association may honor the official credentials presented by students from other colleges having the standard requirements maintained by members of this Association, excepting for the fourth year of their course, but no member shall admit a student to advanced standing without first communicating with the college from which such student desires to withdraw, and receiving from the dean of such college a direct written communication certifying to the applicant's professional and moral qualifications, and to the exact work he had done in said college.

No time credit shall be given to holders of a Bachelor's degree, but subject credit can be given on satisfactory examination. Four years of residence in a medical college shall be required of all candidates for the degree of doctor of medicine.

(Concluded from page 688)

Medical Education.—Candidates for the degree of Doctor of Medicine shall have attended four courses of study in four calendar years, each annual course to have been of not less than thirty-two teaching weeks' duration, and at least ten months shall intervene between the beginning of any course and the beginning of the preceding course. No time credit shall be given to holders of a Bachelor's degree, but subject credit may be given on satisfactory examination. Four years of residence in a medical college shall be required of all candidates for the degree of doctor of medicine.

The entire course of four years shall consist of at least 4,000 hours, divided into the subjects as shown in the table (page 688), and no college shall be recognized that falls below this standard over 20 per cent. in any one branch or over 10 per cent. in the total. Laboratory or clinic hours may be substituted for didactic hours.

Each student shall be obliged to attend 80 per cent. of the exercises in every annual course of study for which he seeks credit. No student shall be given credit on examination unless he attains a grade of at least 70 per cent., or its equivalent, in any other marking system. And no student shall be graduated unless he shall have attained a passing grade in each and all subjects of the required curriculum.

A college which gives less than a four years' course of study, but does not graduate students, and is possessed of other required qualifications, may be admitted to membership.

Each medical college in membership in the Association shall print in every annual catalogue or announcement a table of the total number of hours work given in said college, arranged both by subjects and years.

The following colleges are members of the Association: College of Physicians and Surgeons, Los Angeles, Cal.; Leland Stanford Junior University College of Medicine, Palo Alto and San Francisco, Cal.; University of California, Medical Department, Berkeley, Los Angeles, and San Francisco, Cal.; University of Colorado, School of Medicine, Boulder, Colo.; Denver and Gross College of Medicine, Denver, Colo.; George Washington University Department of Medicine, Washington, D. C.; Georgetown University School of Medicine, Washington, D. C.; Howard University Medical Department,

Washington, D. C.; American Medical Missionary College, Battle Creek, Mich., and Chicago, Ill.; College of Physicians and Surgeons, Chicago, Ill.; Indiana University School of Medicine, Bloomington and Indianapolis, Ind.; Drake University College of Medicine, Des Moines, Iowa; State University of Iowa, College of Medicine, Iowa City, Iowa; Kansas Medical College, Topeka, Kan.; University of Kansas, School of Medicine, Lawrence, Kan.; University of Louisville, Medical Department, Louisville, Ky.; Tulane University, Medical Department, New Orleans, La.; Baltimore Medical College, Baltimore, Md.; College of Physicians and Surgeons, Baltimore, Md.; Johns Hopkins University, Medical Department, Baltimore, Md.; University of Maryland School of Medicine, Baltimore, Md.; Harvard Medical School, Boston, Mass.; Tufts College Medical School, Boston, Mass.; Detroit College of Medicine, Detroit, Mich.; University of Michigan, Department of Medicine and Surgery, Ann Arbor, Mich.; University of Mississippi Medical Department, Oxford, Miss.; University of Missouri Department of Medicine, Columbia, Mo.; University Medical College, Kansas City, Mo.; St. Louis University Medical Department, St. Louis, Mo.; Washington University Medical Department, St. Louis, Mo.; Washington University Medical Department, Omaha, Neb.; University of Buffalo, Medical Department, Buffalo, N. Y.; University and Bellevue Hospital Medical College, New York, N. Y.; Cornell University Medical College, New York, N. Y.; University of North Carolina Medical Department, Chapel Hill, N. C.; Wake Forest College School of Medicine, Wake Forest, N. C.; University of North Dakota Medical Department, University, N. D.; Cleveland College of Physicians and Surgeons, Cleveland, Ohio; Western Reserve University Medical College, Cleveland, Ohio; Starling-Ohio Medical College, Columbus, Ohio; State University of Oklahoma School of Medicine, Norman, Okla.; Meharry Medical College, Nashville, Tenn.; Vanderbilt University, Medical Department, Nashville, Tenn.; Medical College of Virginia, Richmond, Va.; University College of Medicine, Richmond, Va.; University of West Virginia Medical Department, Morgantown, W. Va.; University of Wisconsin College of Medicine, Madison, Wis.

The secretary-treasurer of the Association is Dr. Fred C. Zapffe, 3431 Lexington Street, Chicago.

CHANGES IN COLLEGES IN TEN YEARS

COLLEGES MERGED

1901

Marion-Sims College of Medicine, St. Louis, Mo., united with the St. Louis Medical College (now the St. Louis College of Medicine) and the Columbian Medical College, Kansas City, Mo., merged into the Medico-Chirurgical College of Kansas City, Missouri.

1902

Denver College of Medicine and the Gross Medical College, both of Denver, Colo., united, forming the Denver and Gross College of Medicine.
Dunham Medical College, Chicago, merged into the Hering Medical College, Chicago.
Hahnemann Medical College of Kansas City University and the Kansas City (Mo.) Homeopathic Medical College united, forming the Kansas City Hahnemann Medical College.

1903

National University Medical Department, Washington, D. C., absorbed by the Columbian University Medical Department (now the George Washington University, Department of Medicine).
Medical Department State University, Louisville, Ky., absorbed by the Louisville National Medical College.
Saginaw Valley (Michigan) Medical College absorbed by the Michigan College of Medicine and Surgery of Detroit.

1904

Chicago Homeopathic Medical College merged into the Hahnemann Medical College and Hospital, Chicago.
Dallas (Texas) Medical College, merged into the Baylor University College of Medicine, Dallas, Texas.

1905

Medical College of Indiana and the Central College of Physicians and Surgeons, both of Indianapolis, merged with the Fort Wayne College of Medicine, forming the Indiana Medical College, School of Medicine of Purdue University, Indianapolis.
The College of Physicians and Surgeons of Kansas City, Kansas, the Medico-Chirurgical College of Kansas City, Mo., and the Kansas City (Missouri) Medical College merged into the Central Medical College of the University of Kansas.
The Central Medical College of the University of Kansas, both of St. Joseph, Mo., united to form the Ensworth-Central Medical College, which has since resumed the name of Ensworth Medical College.

1907

The State College of Physicians and Surgeons, Indianapolis, was taken over by the Indiana University School of Medicine as its clinical department.
The Louisville Medical College and the Hospital College of Medicine, both of Louisville, Ky., united to form the Louisville and Hospital Medical College.
The Kentucky University Medical Department was merged into the University of Louisville Medical Department.
The Starling Medical College and the Ohio Medical University of Columbus, Ohio, merged, forming the Starling-Ohio Medical College.

1908

Indiana Medical College, School of Medicine of Purdue University, Indianapolis, was merged into the Indiana University School of Medicine.
Keokuk (Iowa) Medical College, College of Physicians and Surgeons, merged into Drake University College of Medicine, Des Moines, Iowa.
Kentucky School of Medicine and the Louisville and Hospital Medical College were both merged into the University of Louisville Medical Department.
Minneapolis College of Physicians and Surgeons, the Medical Department of Hamline University, was merged into the University of Minnesota, College of Medicine and Surgery.

1909

The University of Southern California College of Medicine was taken over by the University of California as its Los Angeles Medical Department.
The Medical College of Ohio and the Miami Medical College merged, forming the Ohio-Miami Medical College of the University of Cincinnati.
The University of Nashville Medical Department and the University of Tennessee Medical Department united to form the Medical Department of the Universities of Nashville and Tennessee.

1910

Denver and Gross College of Medicine has united with the University of Colorado, School of Medicine.
Illinois Medical College has been merged into the Bennett Medical College, which is now the Medical Department of Loyola University.
The Cleveland College of Physicians and Surgeons has been merged into the Western Reserve University Medical Department.
Pulte Medical College of Cincinnati, Ohio, has been moved to Cleveland and united with the Cleveland Homeopathic Medical College, forming the Cleveland-Pulte Medical College.

COLLEGES SUSPENDED

1900

National Normal University, College of Medicine (Ohio).

1901

Northwestern University, Chicago, Ill.

University of Tennessee, Medical Department.
University of the South.

1910

Epworth College of Medicine.
Chattanooga Medical College.
* Closed by merger.
1. Exposed as fraudulent.
2. Declared not in good standing by the Illinois State Board of Health.

NEW COLLEGES

1900

Eclectic Medical College of Indiana, Indianapolis, Ind.
Hahnemann Medical College of the Kansas City (Missouri) University.
Twentieth Century Medical College, Guthrie, Okla.
Knoxville Medical College, Knoxville, Tenn.
University of West Tennessee, Medical Department, Memphis.
Dallas Medical College, Dallas, Tex.
University of Dallas, Medical Department, Dallas, Tex.
(Now the Baylor University, College of Medicine).

1901

Chicago Eclectic Medical College.
(Now the Chicago College of Medicine and Surgery).
Marion-Sims-Beaumont College of Medicine, St. Louis.
(Now the St. Louis University, School of Medicine).
Temple University Department of Medicine, Philadelphia.

1902

Oakland College of Medicine and Surgery, Oakland, Cal.
Denver and Gross College of Medicine, Denver, Colo.
Kansas City Hahnemann Medical College, Kansas City, Mo.
Wake Forest College, School of Medicine, Wake Forest, N. C.
Gate City Medical College, Texarkana, Tex.
Physio-Medical College of Texas, Dallas, Tex.
West Virginia University, College of Medicine, Morgantown.

1903

College of Physicians and Surgeons, Los Angeles, Cal.
Dearborn Medical College, Chicago.*
University of Mississippi, Medical Department, Oxford.
Bell Medical College (later the College of Physicians and Surgeons)
Dallas, Tex.*
Southwestern University Medical College, Dallas, Tex.

1904

International Medical Missionary College, Atlanta, Ga.*
Epworth College of Medicine, Oklahoma City, Okla.*

1905

Atlanta School of Medicine, Atlanta, Ga.
Indiana Medical College, Indianapolis.††
(Another college by the same name was organized in 1869).
Indiana University School of Medicine, Bloomington.
Ensworth Central Medical College, St. Joseph, Mo.‡
(Has since resumed the name of Ensworth Medical College).
Nebraska College of Medicine, Lincoln, Neb.*
Fordham University School of Medicine, New York City.
University of North Dakota, College of Medicine.

1906

College of Physicians and Surgeons, Little Rock, Ark.
State College of Physicians and Surgeons, Indianapolis.†
Mississippi Medical College, Meridian, Miss.
College of Physicians and Surgeons, Memphis, Tenn.
University of Utah, Department of Medicine.

1907

Reliance Medical College, Chicago.
Louisville and Hospital Medical College, Louisville, Ky.††
Hippocratean College of Medicine, St. Louis.*
Starling-Ohio Medical College, Columbus, Ohio.‡
Oklahoma Medical College, Oklahoma City, Okla.*
University of South Dakota, College of Medicine.
University of Wisconsin, Medical School.
Philippine Medical School, Manila, P. I.

1908

Hospital Medical College, Atlanta, Ga.
College of Medical Evangelists, Loma, Linda, Cal.
Ohio-Miami Medical College of the University of Cincinnati.†
Universities of Nashville and Tennessee, Medical Department.†

1910

Cleveland-Pulte Medical College, Cleveland, Ohio.‡

* Has since become extinct.

† Closed later by merger.

‡ Organized by merger.

COLLEGE NOTES

Endowments and New Buildings

Connecticut.—Yale University received \$500,000 through a bequest from the late Levi I. Shoemaker, of Wilkes-Barre, for the use of the Yale Medical School.

California.—Cooper Medical College, San Francisco, received \$5,000 through the will of Mrs. Myrick.

Illinois.—A new building for Bennett Medical College, now the Medical Department of Loyola University, Chicago, has been erected at a cost of \$60,000, this sum being contributed by physicians.

Iowa.—A sum of \$150,000 was raised by popular subscription for Drake University College of Medicine, Des Moines, to make needed improvements and for current expenses.

Maryland.—The new Phipps Dispensary has been erected on the hospital grounds of Johns Hopkins University Medical School at a cost of approximately \$500,000.

Minnesota.—Three new buildings have been erected for the College of Medicine of the University of Minnesota at a total cost of \$565,000. One of these was the Elliott Hospital, named after Dr. A. F. Elliott, through whose bequest of \$125,000, supplemented by \$40,000 from an appropriation by the state legislature, the building was erected. The two other buildings were the new Institute of Anatomy and a new medical building, each costing approximately \$200,000.

Missouri.—St. Louis University, School of Medicine, was the recipient of \$20,000 from Ambassador Richard C. Kerens, to be used as an endowment fund for free beds in the Rebekah Hospital.

Approximately \$3,000,000 was received by Washington University Medical Department from William K. Bixby, Adolphus Busch, Edward Mallinkrodt and Dr. Robert S. Brookings, for the construction of the new medical buildings on Kings Highway. Counting the value of the hospitals which were also transferred to Washington University, the entire gift came to about \$6,000,000.

Nebraska.—Plans have been accepted for the new group of medical buildings to be erected at Omaha for the College of Medicine of the University of Nebraska.

The John A. Creighton Medical College has erected a new medical building on Fourteenth Street, at a cost of \$60,000.

New York.—Columbia University, College of Physicians and Surgeons, received approximately \$3,000,000 from William K. Vanderbilt, George J. Gould, Frank A. Munsey and others, to be used in the erection of new medical buildings adjoining the University Campus at Morningside Heights. Another gift of \$15,000 was received from William D. Sloan to erect a new addition to Sloan Maternity Hospital and \$18,000 was received from the children of Dr. Abraham DuBois, who was a graduate of the College of Physicians and Surgeons, for the establishment of a fellowship in memory of their father.

A new addition to the building of the University and Bellevue Hospital Medical College has been erected at a cost of \$65,000. Also a gift of \$100,000 was received from Mrs. Helen Hartley Jenkins to endow the chair of medicine.

Section by section the old Long Island College Hospital has been torn down and replaced by a new strictly modern structure. The last section is now approaching completion. The cost of the new structure was approximately \$2,000,000.

A new building is being erected by Fordham University School of Medicine, which will cost about \$1,000,000 when completed.

Donations amounting to \$25,000 have been received by the New York Homeopathic Medical College, to be used for changes in the college building and for the improvement of the laboratories.

Cornell University received \$50,000 from Andrew Carnegie to be used in the enlargement of the laboratory for chemical research.

Ohio.—Western Reserve University received \$250,000 from Mr. H. M. Hanna, as an addition to the endowment of the medical department. The income will be used to place the clinical professorships on a modern university basis.

A fund of \$45,000 was donated by the friends of the late Dr. Eichberg, to endow the Joseph Eichberg chair of physiology in the Ohio-Miami Medical College of the University of Cincinnati. The chair was established last December (1909).

A new college building has been erected by the Eclectic Medical Institute (now College), Cincinnati, at a cost of \$50,000.

Pennsylvania.—Gifts amounting to \$800,000 were received by the University of Pennsylvania for the endowment of the Henry Phipps Institute for the study and prevention of tuberculosis and for the endowment of the clinical chairs. A new addition to the University of Pennsylvania Hospital was opened May 12, which was built at a cost of \$37,000.

A new college building is now being erected by the Medical Department of the University of Pittsburgh. The approximate cost when completed will be \$200,000.

Jefferson Medical College received \$60,000 from Mrs. Maria Gross Horwitz, daughter of the late Dr. Samuel D. Gross, for the purpose of founding a chair of surgery, in memory of her father. Another gift from Daniel Baugh, a member of the board of trustees, is the property including the building formerly occupied by the Pennsylvania Dental School, which is valued at \$50,000.

South Carolina.—The medical building of the Medical College of the State of South Carolina has been extensively remodeled.

Vermont.—The Vermont legislature gave \$10,000 to the University of Vermont to enable it to assume full responsibility, financially and otherwise, for the Medical Department.

Virginia.—A sum of \$10,000 has been donated toward the new building for the University College of Medicine, Richmond, to replace the one destroyed by fire last January.

Canada.—New medical buildings, at a cost of \$750,000, have been erected by McGill University to replace the one destroyed by fire in 1907. Lord Strathcona, who donated the site on which the building was erected, also gave \$500,000 toward the building itself.

Full Time Instructors.—The Atlanta College of Physicians and Surgeons has just added to its faculty three full-time, salaried instructors. Dr. Justin F. Grant, professor of anatomy and pathology in the medical Department of the University of West Virginia, has been secured for the chair of anatomy; Dr. George Bachman, associate professor of physiology in the Jefferson Medical College of Philadelphia, for the chair of physiology and Dr. John Funke, of Jefferson Medical College of Philadelphia, as adjunct professor of pathology, bacteriology and hygiene.

Special Preliminary Year.—A special preliminary year devoted to physics, chemistry, biology and modern languages has been established by several medical colleges, including Fordham University, School of Medicine; St. Louis University, School of Medicine and Ohio-Miami Medical College of the University of Cincinnati.

COLLEGES LISTED AS ACCEPTABLE (CLASS A)

By the Council on Medical Education of the American Medical Association

1. Giving a complete four-year course:

- ALABAMA**
University of Alabama Medical Department.
- CALIFORNIA**
Leland Stanford Junior University Medical Department (Cooper Medical College).
University of California, Medical Department, San Francisco-Los Angeles.
- COLORADO**
Denver and Gross College of Medicine.
University of Colorado, School of Medicine.
(These two colleges have been merged and will constitute the School of Medicine of the University of Colorado.)
- CONNECTICUT**
Yale Medical School.
- DISTRICT OF COLUMBIA**
George Washington University, Department of Medicine.
Georgetown University, School of Medicine.
- ILLINOIS**
Northwestern University Medical School.
Rush Medical College, University of Chicago.
College of Physicians and Surgeons, Chicago.
Hahnemann Medical College and Hospital, Chicago.
- INDIANA**
Indiana University School of Medicine.
- IOWA**
State University of Iowa, College of Medicine.
State University of Iowa, Homeopathic College.
Drake University, College of Medicine.
- KANSAS**
University of Kansas, School of Medicine.
- KENTUCKY**
University of Louisville, Medical Department.
- LOUISIANA**
Tulane University of Louisiana, Medical Department.
- MAINE**
Medical School of Maine.
- MARYLAND**
Johns Hopkins University of Medicine and Surgery.
University of Maryland, College of Physicians and Surgeons, Baltimore.
Baltimore Medical College.
- MASSACHUSETTS**
Boston University, School of Medicine.
Harvard Medical School.
Tufts College Medical School.
- MICHIGAN**
University of Michigan, Department of Medicine and Surgery.
University of Michigan, Homeopathic College.
Detroit College of Medicine.
- MINNESOTA**
University of Minnesota, College of Medicine and Surgery.
- MISSOURI**
St. Louis University, School of Medicine.
Washington University Medical Department.
University Medical College, Kansas City.
- NEBRASKA**
Creighton Medical College.
University of Nebraska, College of Medicine.
- NEW HAMPSHIRE**
Dartmouth Medical School.
- NEW YORK**
Albany Medical College.
Columbia University, College of Physicians and Surgeons.
Cornell University Medical College.
Fordham University, School of Medicine.
Long Island College Hospital.
New York Homeopathic Medical College and Hospital.
Syracuse University, Medical Department.
University and Bellevue Hospital Medical College.
University of Buffalo, Medical Department.
- OHIO**
Ohio-Miami Medical College, Medical Department, University of Cincinnati.

SATURDAY, AUGUST 20, 1910

MEDICAL EDUCATION IN THE UNITED STATES

The tabulated statistics herewith presented (pages 682 to 690) are for the year ending June 30, 1910, and are based on signed reports received directly from the medical colleges, or from other reliable sources. We wish here to acknowledge the courtesy and cooperation of the officials of the medical colleges which have made the compilation of these complete statistics possible.

STATISTICS OF COLLEGES

On pages 682 to 684 is Table 1, which gives all the colleges in session during 1909-10, the population of the city in which each college is located, the number of students, men and women, registered during the year, the number of 1910 graduates, men and women, the number of graduates holding collegiate degrees, the number of teachers for each college, the number of weeks of actual work in the college year, the total fees for each year, the executive officer of the college and the dates of beginning and ending of the next session. The figures in heavy-faced type show the totals by states. Beginning on page 667 are given essential facts concerning all medical colleges, arranged by states.

NUMBER OF MEDICAL STUDENTS

The total number of medical students (matriculants) in the United States for the year ending June 30, 1910, excluding special students, was 21,526, a decrease of 619 below 1909, a decrease of 1,076 below 1908, and a decrease of 6,616 below 1904, when the highest number of students was enrolled. It is the lowest number since THE JOURNAL began compiling these statistics in 1900. Of the total number of students, 20,136 were in attendance at the regular colleges, 867 at the homeopathic, 455 at the eclectic, 49 at the physiomedical and 19 at unclassifiable colleges. The attendance at the regular colleges shows a decrease of 418 below that of last year, of 800 below 1908 and 2,167 below 1907. In the homeopathic colleges there was a decrease of 32 below the attendance of 1909. The eclectic colleges show an increase of 42 over 1909, but a decrease of 24 below 1908 and of 90 below 1907. The physiomedical colleges had 49 this year, as compared with 52 in 1909 and 90 in 1908.

TABLE 4.—MEDICAL COLLEGE ATTENDANCE

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med.	Non-descript.	Total.
1880.....	9,776	1,220	830	...	...	11,826
1890.....	13,521	1,104	719	...	...	15,404
1900.....	22,710	1,509	522	...	...	25,171
1901.....	23,846	1,683	661	80	144	26,417
1902.....	24,878	1,617	765	91	150	27,501
1903.....	24,930	1,498	848	149	190	27,615
1904.....	23,662	1,309	1,014	123	234	28,142
1905.....	24,119	1,104	578	114	232	26,147
1906.....	23,116	1,085	644	110	249	25,204

1908.....	20,936	891	479	50	206	22,602
1909.....	20,554	899	413	52	227	22,145
1910.....	20,136	867	455	49	19	21,526

GRADUATES

The total number of graduates for the year ending June 30, 1910, was 4,436, a decrease of 6 below 1909, a decrease of 305 below 1908 and of 544 below 1907. It is the lowest number graduating since THE JOURNAL began compiling these statistics, and is 1,311 less than in 1904, when there were 5,747 graduates. The percentage of graduates to matriculants was 20.7, as compared with 20.1 in 1909 and 21.0 in 1908. The number of graduates from the regular colleges was 4,113, or 23 more than in 1909, but 257 less than in 1908. From the homeopathic colleges there were 179 graduates, or 30 less than in 1909 and 36 less than in 1908. The eclectic colleges graduated 114, or 30 more than last year but 2 less than in 1908. The physiomedical colleges had 16 graduates this year, as compared with 15 last year and 12 in 1908.

TABLE 5.—MEDICAL COLLEGE GRADUATES

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med.	Non-descript.	Total.
1880.....	2,673	380	188	..	..	3,241
1890.....	3,553	380	221	..	..	4,454
1900.....	4,715	413	86	..	..	5,214
1901.....	4,879	387	148	18	12	5,444
1902.....	4,498	336	138	16	11	4,990
1903.....	5,088	420	149	24	17	5,698
1904.....	5,190	371	146	20	20	5,747
1905.....	5,126	276	153	22	23	5,600
1906.....	4,841	286	186	22	39	5,364
1907.....	4,591	225	121	11	32	4,980
1908.....	4,370	215	116	12	28	4,741
1909.....	4,050	209	84	15	44	4,442
1910.....	4,113	179	114	16	14	4,436

Of the 4,436 medical graduates, 680, or 15.3 per cent., were reported to hold also degrees in arts or science, as compared with 15.6 per cent. in 1909 and 17.3 per cent. in 1908. Although, in recent reports on medical education, Illinois is referred to in rather uncomplimentary terms on account of its having a number of inferior medical schools, this clearly does not apply to all the Illinois colleges, since of the 680 medical graduates holding collegiate degrees, 133, or about 20 per cent., came from Illinois colleges. It is expected that in the future the percentage of college graduates entering medicine will increase rather than decrease, since more medical schools are requiring some college work for admission.

WOMEN IN MEDICINE

During the past year there were 907 women studying medicine, a decrease of 14 below 1909, but an increase of 72 over 1908. The percentage of all medical students

was 4.2, the same as last year. There were 157 women graduates this year, or 3.5 per cent., of all graduates. In 1909 there were 921 women students and 162 graduates, while in 1908 there were 835 women students and 185 graduates. Of all the women matriculants, 155 (17.1 per cent.) were in attendance at the 3 medical colleges for women, as compared with 169 (18.4 per cent.) in 1909 and 186 (22.3 per cent.) in 1908. From the 3 women's colleges, there were 41, or 26.1 per cent., of all women graduates, as compared with 33 (20.3 per cent.) in 1909 and 46 (24.9 per cent.) in 1908. The remaining 752 (82.9 per cent.) were matriculated in coeducational colleges.

TABLE 6.—WOMEN IN MEDICINE

Year.	Total women students.	Percentage of all students, both sexes.	Total women graduates.	Percentage of all graduates, both sexes.	Women's colleges.	Students.	Percentage of all women students. 1910	907	4.2	157	3.5	3	155	17.1	41	26.1	82	752	82.9	116	73.9

NUMBER OF COLLEGES

Since June 30, 1909, 12 colleges (mentioned on page 691) have either suspended or have merged into others and 1 new college was established, making a net decrease of 11 colleges since last year, the total now being 133. The regular colleges number 111, a decrease of 6 since last year. The homeopathic colleges number 13, a decrease of 1. Of the eclectic colleges, 1 was reorganized recently as a regular college, leaving 7. There is now only 1 physiomedical college and 1 school which is unclassifiable since it offers to teach two or more systems of medicine.

TABLE 7.—MEDICAL COLLEGES

Year.	Regular.	Homeopathic.	Eclectic.	Physio-Med.	Non-descript.	Total.
1880.....	72	12	6	..	..	90
1890.....	93	14	9	..	..	116
1900.....	121	22	3	..	..	151
1901.....	124	21	10	..	..	155
1902.....	121	20	10	3	2	156

1906.....	130	13	9	3	1	161
1907.....	131	17	8	3	2	161
1908.....	123	10	8	3	3	152
1909.....	117	14	8	1	3	143
1910.....	121	13	7	1	1	143

During the past ten years, 70 medical colleges (see page 691) have ceased to exist, either through merger or otherwise. During the same time, however, 50 new colleges have been organized, leaving a net decrease of 20. While the total number of colleges is smaller, the percentage of higher-grade, stronger medical colleges has been considerably increased.

LENGTH OF TERMS

The length of term of each college fluctuates somewhat from year to year, but on the whole, during the last several years there has been a decided lengthening of college terms. This has reference to the weeks of actual work, inclusive of holidays. Only 2 colleges this year report sessions shorter than twenty-seven weeks, as compared with 4 last year. In 1901 there were 58 which held sessions of less than twenty-seven weeks. Of those having sessions of twenty-seven or twenty-eight weeks, the number is 8 this year, or 9 less than last year, and 38 less than in 1903. There are 19 colleges claiming courses of twenty-nine or thirty weeks of actual work, and 42 claiming courses of thirty-one or thirty-two weeks. One hundred and two, or over 76 per cent., of all colleges now claim to require from 31 to 36 weeks of actual work, exclusive of holidays, as compared with 30 per cent. in 1901, with 42 per cent. in 1904, and 68 per cent. last year. The 2 colleges claiming courses longer than thirty-six weeks are night schools. It would doubtless require twelve or fourteen years of the usual night-school study, however, to secure the equivalent of four years of thirty weeks each in the better day colleges.

TABLE 8.—COLLEGE TERMS

Year.	23 to 26 weeks.		27 to 28 weeks.		29 to 30 weeks.		31 to 32 weeks.		33 to 34 weeks.		35 to 36 weeks.		Ov. 36 weeks.

TUITION AND OTHER FEES

Special attention is called in Table 1 to the total amount charged by the various colleges for tuition, matriculation, laboratory and graduation fees *per annum* for each student. In Table 9, the 133 colleges have been grouped according to the amount of fees charged.

TABLE 9.—COLLEGE FEES

Total Fees.	Number of Colleges.			
	Class A.*	Class B.	Class C.	Total.
\$ 50 or less.....	5	1	1	7
50 to \$ 75.....	9	..	3	12
75 to 100.....	5	7	15	27
100 to 125.....	17	14	6	37
125 to 150.....	13	4	3	20
150 to 175.....	8	3	..	11
175 to 200.....	6	2	..	8
200 or above.....	6	..	..	6

* Based on the classification of medical colleges prepared by the Council on Medical Education.

Nineteen charge fees of \$75 or less per year, 64 colleges charge between \$75 and \$125, 36 charge between \$125 and \$175, and 14 colleges charge above \$175. Of

the 19 colleges charging \$75 or less, 14 or 74 per cent. have been listed among Class A (acceptable) colleges by the Council on Medical Education.¹ Among these colleges are the schools of medicine of the state universities of Colorado, Iowa, Mississippi, Missouri, North Carolina, North Dakota, South Dakota, Utah and West Virginia. On the other hand, 24 colleges listed by the Council in Class C charge fees of over \$100 per year for each student. This clearly refutes the assertion made by some inferior colleges that they are needed for the sake of "the poor boy who wants to study medicine." Although 20 colleges listed in Class A charge fees ranging from \$150 to \$275 per year for each student, the actual expense for teaching that student in these colleges ranges from \$300 to \$600 or even more per year.

DISTRIBUTION OF MEDICAL STUDENTS

Table 2, on pages 686 to 689, shows from what states the students come who were in attendance at each medical college during the session of 1909-10. The influence of the proximity of the medical school is seen in the fact that states having medical colleges contribute more students in proportion to the population than those which have no colleges. A comparison of this table with the large tables based on state board examinations² which show the distribution of the alumni of each college, is interesting. The college which has widely distributed alumni usually has a student body from an equally large number of states.

Only one state contributed over 2,000 students this year, this being New York with 2,120. Pennsylvania contributed 1,990 and Illinois 1,959. The next states, in the order of the number of students contributed, are: Ohio, 902; Massachusetts, 809; Missouri, 807; Texas, 719, and Iowa, 702. Four states had less than 20 each, these being New Mexico and Wyoming, each 11, Nevada 6 and Arizona 5. There were 54 students from Hawaii, Porto Rico and the Philippine Islands, and 563 students from foreign countries.

MIGRATION OF MEDICAL STUDENTS

Table 3, on page 690, shows the number of students of each section of the country who attended medical schools of that section and the number who attended medical colleges of other sections. Section A gives the figures for students from the eastern states; Section B, for students from the middle states; Section C, for students from the western states, and Section D, for students from the southern states. Figures are given for the three college years, 1907-8, 1908-9 and 1909-10. The differences in the figures for the three years show the fluctuation due to the exit of the graduating classes, to the ingress of the new freshmen and to the comparatively few who left the colleges of one section

and went to those of other sections. At the bottom of Section D appear the average totals for the three years. Percentages are given in order to permit of comparisons. The eastern section has long held the largest place in medical education, and, as would be expected, still has the smallest percentage of students leaving to attend colleges in other sections, the percentage of those remaining in the eastern section being 92.1. The middle states are a close second, with 90.6 per cent. of their own resident students studying medicine in that section. The western section, having the smallest number of colleges, naturally has a larger proportion of students attending in other sections. Of the students who migrate from the middle and southern sections, the largest proportions go east, while of those from the western section, the largest proportion attends colleges of the middle section. Altogether 2,555 students attended colleges outside of the section in which they lived. Of this number, 1,092, or 42.7 per cent., went to the eastern section; 1,020, or 39.9 per cent., went to the middle section; 304, or 11.9 per cent., went to the southern section, and 139, or 5.5 per cent., went to the western section.

THE YEAR IN MEDICAL EDUCATION

The special features of the past year in medical education have been the publication of a classified list of medical colleges by the Council on Medical Education after a six years' investigation, and the publication of the report on medical education by the Carnegie Foundation for the Advancement of Teaching. The report of the Carnegie Foundation, which is more severe than that of the Council, bears out the claim of the latter that its markings were very lenient. The publication of these two reports is sure to result in good to medical education. Prospective medical students now have the information that will enable them to select the better colleges, and, therefore, colleges which adhere to reasonably high standards, and are fairly well equipped, will be benefited. These reports show how each college ranks as compared with other colleges; the needed improvements have been pointed out and the way has been opened for further development.

A survey of the entire field of medical education shows that marked progress has been made during the last few years. As is noted in another column,³ there are 35 colleges which after this fall will be requiring one or more years of collegiate work for admission, and eight state licensing boards which have adopted similar requirements. Numerous mergers of medical colleges have been brought about, better equipped laboratories have been provided, better trained teachers have been employed, new buildings have been erected and increased endowments secured. The outlook for the future of medical education in this country is indeed most encouraging.

1. For complete classification see THE JOURNAL A. M. A., June 18, 1910, pp. 2061 and 2062.

2. THE JOURNAL A. M. A., May 21, 1910, p. 1740.

3. Pages 680 and 681.

ANOTHER MEDICAL JOURNAL PREFERS DECENCY
TO DOLLARS

The medical journal which, being the official organ of either a state or national organization and having the financial and moral support of the organized profession it represents, decides to throw out the advertisements of all preparations exploited dishonestly and untruthfully, deserves credit. The owners of a medical journal who, at the height of a campaign for clean advertising, when enthusiasm runs high and before the experiment has been tried out, decide to do the same thing, deserve even greater credit—although the spectacular element tends to qualify it. But the owners of a medical journal who, after seeing the experiment tried—with disastrous results in many cases—and knowing the terrific struggle for a journal's mere existence which such a course entails, soberly and calculatingly determine to eliminate from their advertising pages all unworthy medicinal products—such men are making a sacrifice in the interests of truth and decency that is truly heroic.

While this movement for honest advertising of medicinal products is confined to no one section of the country, yet the South seems to be leading. No fewer than three southern medical journals have placed themselves in this class. Two of these¹ have already been referred to in *THE JOURNAL*. The latest one to cross the Rubicon is the *Gulf States Journal of Medicine and Surgery*, which in its June issue states the case in plain, unmistakable terms. After reviewing briefly the sphere which their journal is attempting to fill, the editors say:

We have reached the conclusion that the only way to be absolutely sure to admit no unworthy proprietary medicine advertisement, and that those we do admit will be precisely as advertised, is to accept as final the conclusions of the Council on Pharmacy and Chemistry established by the American Medical Association, and be guided thereby. There can be no doubt of its sincerity. It has done an immense amount of investigation and analysis, and though, being human, it doubtless errs sometimes, yet its opportunities for forming sound opinions exceed by far any other ways at our disposal. Their conclusions, like those of the highest courts of review, are the soundest obtainable.

Then follows this announcement in ten-point capitals:

From this date the *Gulf States Journal of Medicine and Surgery*, journal of the Southern Medical Association, will neither make nor renew a contract for advertising any proprietary medicine which is not recognized by the aforesaid Council.

The editors of this journal are evidently under no delusion as to what such a step means; they realize that to reject 50 per cent. of their present advertising patronage is not a thing to be looked at lightly. They say:

We know what we are doing. We are aware that no medical journal can be self-sustaining without a large advertising list. We know that this step may be the first towards failure. But if we cannot publish a journal whose readers will know that whatever its editors or advertisers say is untainted with either deceit or fraud, without going down in failure, then down we will go! There is no dishonor in such a failure!

1. The Southern Medical Journal and the Old Dominion Journal of Medicine and Surgery. The former now has but one advertisement to which objection can be raised, while the latter has but two.

But we shall not fail! Southern doctors want the sort of medical magazine that we desire to supply, and they will stand up to us through this fight. As rapidly as the circumstances will admit, our readers will observe the change in our advertising pages.

Sink or swim, survive or perish, we have planted the standard of the *Journal* on the heights, and shall stand by it.

The problem is now "up to" the medical profession of the South. We believe that a section of the country which produces such editors as these also produces men who will support the principles these editors stand for. The South, in leading the country in this fight for decency and truth, has merely lived up to its traditions; and we believe that, in placing principles before pelf and conscience before commercialism, it is putting itself in the vanguard of journalistic progress. We would urge every physician to show in a concrete way his appreciation of the stand that has been taken. Subscribe for these journals²; a large and influential subscription list assures a liberal advertising patronage and this in turn makes possible a virile and aggressive journal.

The time has come when the medical profession must wake up to a fact that it has very largely ignored in the past: It costs money to publish a medical journal. If physicians—in whose interests these journals are published—are not willing to support them, the proprietary people stand ready to relieve physicians of the necessity of doing so. But—and this is the crux of the whole matter—the journals will naturally favor, and advocate if necessary, the interests from which they receive their chief support. If the medical profession wants really independent medical journals—independent of all interests except those they are supposed to represent—it must pay for them.

VISUAL TESTS AND THE PUBLIC SERVICES OF
THE UNITED STATES

The prevention of accidents in connection with transportation systems is an important subject for the attention of the medical profession. Owing to the rapid growth of the country the railroad trackage and the system of waterways have grown almost beyond belief. As one result, the regulation of a number of details looking to the protection of the public has not as yet received that attention which its relative importance deserves. Such progress as has been made is largely due to the labors of committees appointed by the American Medical Association and its sections. As an instance the Section on Ophthalmology of the American Medical Association, through a committee, devoted several years to the accumulation of statistics gathered from the important railways of this country, and finally adopted a set of well-matured resolutions embodying rules to govern the visual and hearing tests of transportation employees which were approved by the House

2. The Gulf States Journal of Medicine and Surgery, 905 Van Antwerp Bldg., Mobile, Ala., \$2.00 a year; the Southern Medical Journal, 150 Fourth Avenue North, Nashville, Tenn., \$2.00 a year; the Old Dominion Journal of Medicine and Surgery, 116 East Franklin Street, Richmond, Va., \$2.00 a year.

of Delegates. The regulations they suggested have been adopted by practically all the leading railroads.

In line with this work the chairman in his address¹ before the Section on Ophthalmology at St. Louis, after investigation, reviewed the visual requirements in branches of the public service in which definite standards of vision are essential. These are, chiefly, the United States Army, United States military and naval academies, mercantile marine, the Revenue Cutter Service, the life-saving department, the officials of the Coast and Geodetic Survey and pilots in both the federal and some of the state and municipal services.

One result of this activity was definitely to draw the attention of the War Department to the matter. The Surgeon-General of the Army has appointed a commission, including the chairman of the Section on Ophthalmology, to draft a new series of visual requirements for the United States Army. After careful consideration of the subject and after comparison with standards now in operation in the British and Continental services, the commission drew up a series of requirements that will shortly be submitted for the approval of the General Staff.

In the course of the inquiry into the legal requirements as to vision of mercantile marine pilots it was discovered that only officers of steamers and sailing vessels over 700 tons gross and of vessels over 100 tons carrying passengers are under federal supervision. Bar or branch pilots, as they are called, are under state and municipal authority only. In all sections of these services even the meager rules applicable to vision and to visual tests were honored rather in the breach than in the observance. The Surgeon-General of the Marine-Hospital Service, however, has arranged to apply the proper tests and to request the Department of Commerce and Labor, whose function it is to create proper standards for the purpose, to authorize a thorough examination of the sight of applicants for employment in any branch of this service.

This agitation for improved precautionary measures in our merchant marine will, doubtless, exert a beneficial influence on the pilot service of the various states and municipalities. As Dr. Posey shows, there is much room for improvement. The spectacle of a color-blind or short-sighted officer of a sailing or other vessel practicing his profession in a crowded harbor is far from reassuring. Indeed, a number of disasters at sea directly attributable to defective eyesight of the pilot in charge, were cited in the address.

The visual requirements of officials in the other departments of the public service were, with few exceptions, also found to be inadequate.

With these facts before them the Section on Ophthalmology and the House of Delegates adopted resolutions recommending that a committee be appointed to confer

with the Department of Commerce and Labor and with the Marine-Hospital authorities, with a view to establishing proper visual standards and tests to govern these public servants. When this committee has ended its labors we shall not be, as we now are, exposed to the accusation that the United States lags behind other governments in the protection of its seafaring population.

DOCTORS OF PUBLIC HEALTH (D.P.H.)

While much interest is taken and a vast amount of good work is being done in public health matters, yet we have only recently begun to recognize that such work requires the services of a specialist. And while the courses in our medical schools have been gradually lengthened to include training in bacteriology, in the examination of the blood, the secretions and excretions, as well as more or less instruction in hygiene and sanitation, yet our country lacks trained men to carry on public health work. As a rule the general practitioner or the physician who has had the modern medical training, while immeasurably superior to the mere political henchman, has not measured up to the possibilities of the situation as a sanitarian. There have been notable exceptions to this, but they merely point to the rule; and our failure to reap the full harvest in the field of preventive medicine is due to a considerable extent to this cause. The sanitary sciences have given us many new and useful facts, and present health organizations are daily collecting in their reports much valuable information; and still the field, though fitfully tilled by the kind-hearted philanthropist, by the faddist and by the reformer, is permitted to lie fallow most of the time for want of trained experts to make the practical application.

For years the more enlightened nations, with the exception of our own, have required of their health officers special fitness and training for public health work. In the United States, however, no such provision has been required; in fact, no professional school has so far been in a position to equip men with the special knowledge such work demands. To meet this Harvard has taken an advanced step in offering a degree of Doctor of Public Health (D.P.H.), the work for which will center about the new Department of Preventive Medicine and Hygiene. The new degree is a most practical one; it should prove attractive and will, we hope, be offered soon by other schools.

The new course offers wide opportunity for training in several specialized fields of public health work or the sanitary sciences. The course should qualify those who complete it to continue in research; if their temperament and inclinations fit them for original work; to teach the subject, provided they have the gift of pedagogy, or to administer public health affairs provided they have executive ability. Undoubtedly there is a demand for well-trained health officers. The political health

1. Posey, W. C.: Visual Requirements in the Public Services of the United States, THE JOURNAL A. M. A., Aug. 13, 1910, p. 548.

officer is an anachronism, and the day when the gynecologist, the surgeon or the general practitioner, without special training, can successfully take charge of the health of the state is passing away. A board of health composed of untrained men of business or professional affairs is no longer compatible with the increase of special knowledge. The complications of modern life demand acquaintance with this special knowledge, and we welcome this latest addition to the fellowship of the learned and useful professions.

THE PURIFICATION OF WATER BY HYPOCHLORITES

A large variety of chemical substances have been used in experiments on water purification and a few of them have found their way into practical use. We have several times discussed the employment of ozone in the treatment of public water-supplies and have noted that the relatively high expense and the difficulty of securing uniform production are obstacles to the general introduction of the ozone process on a large scale. Recent experience with other methods of water disinfection is, however, more promising.

In sewage disinfection the use of bleaching-powder, an impure product composed largely of calcium hypochlorites, has been studied rather extensively in Germany, and has been the subject of excellent experimental work by Phelps¹ in this country at Red Bank, N. J., and at Baltimore. It was but a step to apply a similar treatment to polluted drinking-water. Already in 1897 bleaching-powder had been used for this purpose in Maidstone, England, at the time of a typhoid epidemic due to a polluted water-supply. The use of bleaching-powder for the purification of the Jersey City water-supply in 1908-9 drew further attention to the process and was the starting-point of the greatly accentuated interest in this subject that has been shown during the past year. The construction and operation of the disinfecting plant were intrusted to a firm of sanitary experts and their report has been received with merited confidence. The degree of purification effected may be judged from the fact that while the number of bacteria in the raw water ranged from 30 up to 1,600 the treated water contained an average of but 15, and in only one sample out of 455 tests was *Bacillus coli* found in the water delivered.

It is not surprising that results like these have given a strong impetus to the use of the bleaching-powder treatment. A number of American cities have already employed the hypochlorite treatment on a large scale. Among these are Harrisburg, Pa., and Quincy, Ill., where the process has been used in conjunction with the application of coagulants and mechanical filtration. Minneapolis, Montreal, Toronto, and recently Milwaukee have made use of the treatment to check outbreaks of water-borne typhoid fever. The rapid spread of this

method of water purification is indeed one of the most interesting and promising developments of the past two years. Up to the present the method has seemed to grow in favor. The great simplicity of the apparatus necessary for applying the disinfectant makes it possible in an emergency to install a small plant within a few days. The exceedingly low cost of the process, which seems to average less than 40 cents per 1,000,000 gallons, constitutes another important advantage. Thus far no serious objection has been brought against the hypochlorite treatment and there has been a surprising unanimity of favorable judgment from all who have had personal experience with it. If we must have sewage in our water, let us disinfect it before drinking.

Current Comment

A HITHERTO UNPUBLISHED TESTIMONIAL

A layman writes to *THE JOURNAL* asking whether the "D.D.D. Prescription" would have any injurious effect on a person using it and says, regarding this nostrum:

"Have used forty-eight bottles of it for eczema and am not rid of it yet."

He wants to know, "whether this medicine could have a tendency to poison one's blood so that one would lose 14 pounds in flesh and become weak and emaciated, flesh soft and flabby and his condition generally miserable, within two months." As this "dandruff cure" contains 38 per cent. of alcohol and 7 grains of chloral hydrate to the ounce, an affirmative answer to our correspondent's query can hardly be called overdrawn. For a product which, before the Food and Drugs Act made lying on the label illegal, was advertised to "positively and permanently cure eczema," its therapeutic action seems rather slow. Would the manufacturers recommend a change in treatment or another round of 48 bottles? In the words of Jack London: "We are curious to know. We are curious to know."

THE UNTRAINED DOCTOR AND THE PUBLIC HEALTH

An editorial with the above caption appeared in the *Chicago Examiner*, August 12, 1910. This paper had published lists of the graduates of several low-grade medical schools of Chicago, who were practicing in Illinois. One of these graduates wrote to the paper expressing "surprise that a newspaper which has always taken the part of the common people against the trusts," should "make common cause with those who are attempting to create a trust in medical education," and saying that "the right to change one's occupation is one of the blessings which free men enjoy, and a man who has been successful in other lines is just as likely to make a successful medical man; and even if he had been a failure in his previous occupation, it would not prove him a failure in the profession he now follows." The newspaper answered that although it acknowledged the fairness of the doctor's argument

1. Phelps: Water-Supply Paper 229, U. S. Geol. Survey, 1909.

and would not think of singling him out to be held up to public distrust; nevertheless it "does not wish its well-known attitude toward the trusts and the people to be confounded with its desire to throw safeguards around the practice of medicine, and it does not subscribe to the doctrine that a shoemaker must invariably stick to his last." The *Examiner* then continues:

Every man is entitled to change his profession as his inclinations and his talents may dictate. But every man is not entitled to enter boldly on the practice of medicine, merely because he has a leaning that way, has given it a little desultory study, and boasts a diploma that has been obtained by questionable methods or by answering a few stereotyped questions. If there is a trust that keeps incompetent people from fooling with the health and lives of the people, the *Examiner* is for that trust, whatever or wherever it may be.

If there are, here and there, men whose remarkable talents have enabled them to rise to deserved eminence in the medical profession without the full medical instruction and preparation considered safe in the practice, there are unhappily hundreds of others who are totally unqualified and unfit for the trust that is reposed in them. And the *Examiner* comes not to call the righteous but sinners to repentance, the sinners being to a notorious extent the so-called graduates of this meager and inadequate course of training.

And so the *Examiner* renews its politest and sincerest assurances of esteem to all who have changed their professions for other lines of duty and the world's work for which they have been properly prepared and qualified. And it will continue to stand for the exercise of the privilege of restraining ignorance, incompetency and lack of preparation in those who jeopardize human health and endanger human happiness for a mere whim or because it seems a little more profitable to the practitioner. If "a little knowledge is a dangerous thing" it is never more dangerous than in experimenting with the art of healing.

THE DANGER OF WOOD ALCOHOL

It has been pretty well understood that wood alcohol is decidedly unsafe to drink; that even its vapor may jeopardize the eye-sight. To the medical profession especially has this danger been emphasized by the excellent researches of Buller and Wood, which were published in *THE JOURNAL*. Now comes Mueller, the German physiologist, who says that pure methyl alcohol is little more poisonous than ethyl alcohol; that it is the impurities which make methyl alcohol poisonous. It is stated that no systematic experiments have heretofore been made to determine the toxic qualities. The deductions of Mueller do not make methyl alcohol any more safe, but they may lead to a method by which it can be manufactured more free from the impurities referred to. One way of stating the case might be that methyl alcohol is naturally denatured in the process of manufacture.

ABATING THE FLY NUISANCE

The domestic or "typhoid" fly is at present receiving much deserved attention on the part of health boards, the newspapers and the public, all of whom seem to be taking the advice to "swat the fly" whenever he raises his pestiferous head. The determination to exterminate this disease-carrier is becoming strong and it will soon be considered as much of a family disgrace to have flies about the house as it now is to have bedbugs. In addition to inhibiting the multiplication of flies by destroy-

ing their breeding-places, a further means has been noted. Dr. Percy L. Jones, of the Army Medical Corps, reports that flies are comparatively rare in the Philippines because of a species of ant which greedily devours the larvæ of the fly, and he has seen them carry away the pupæ. If this ant has no pernicious habits or qualities as obnoxious as those of the fly, the species might be imported and put to work. Entomologists have found that there are many parasites that prey on the fly, principally in the pupal stage, but evidently they are not widely distributed or numerous enough to produce an abatement of the nuisance.

A RIGHTEOUS NEWSPAPER

Not all metropolitan newspapers put the welfare of their readers above the almighty dollar, but the *Chicago Tribune* is one that is doing this. Some years ago it barred from its columns all medical advertisements that it considered fraudulent. During the current week it has boldly published the names of certain "patent medicines" that are dangerous to infants because of the opiates contained in them. Taking the report of Dr. Kebler of the Bureau of Chemistry as its authority, it prints in blackfaced letters the names of the nostrums that are condemned as unsafe, and in addition to publishing this list in several consecutive issues, it has emphasized the matter editorially. McCutcheon aids in damning these deadly nostrums in a forceful cartoon, one picture representing the "quack" or the thoughtless dealer with a bottle of soothing syrup in his hand, saying, "That will make it stop crying; 50 cents, please;" the other representing the sequel—the mother weeping over an empty cradle. What a change would result if even one paper in each large city had the courage to do as the *Tribune* has done in this instance.

FLORENCE NIGHTINGALE

The death of Florence Nightingale at the age of ninety removes one of the most striking figures of the nineteenth century. Born to wealth and luxury, she early showed a taste for the work to which she later gave her life and lost no opportunity of visiting hospitals and studying the care and nursing of the sick. At that time the profession of nursing was not at all a fashionable occupation and had little attraction for a refined and educated lady. As one of Miss Nightingale's biographers has said, it was considered to be a profession which no decent woman of any rank could follow. In spite of this, after examining all the nursing institutions available to her in her own country she went to the Hospital of the Protestant Sisters of Mercy at Kaiserswerth, Germany, and later to the Sisters of St. Vincent de Paul in Paris. When the Crimean War broke out military nursing was practically an unknown art and anyone who has read William H. Russell's account of conditions in the British hospitals near the seat of war can see how different they were from those of modern days. Miss Nightingale's project was spoken of as an undertaking wholly new to English customs. Her work in the hospitals of Scutari and Balaklava was

pioneer work in nursing in military hospitals, but she showed such capacity for management in spite of specially difficult conditions that she made it a success. Modern military nursing, among English-speaking peoples at least, owes its origin to Florence Nightingale. She captured English opinion in spite of the prejudice of a nation which is none too ready to take up with novelties of any kind, and her name has become a household word. Though after the war she was an invalid, her activities did not cease; she was constantly consulted in all matters of nursing for fifty years or more and her writings and utterances have carried weight wherever the English language is spoken. Her advice was sought and taken in hospital construction during our Civil War and during the Franco-Prussian war, and many of the plans for the building and organization of hospitals in England passed through her hands. The training schools for nurses which she established at St. Thomas' Hospital and King's College Hospital in London have been the models for all similar institutions since established in Great Britain and America. As a writer on sanitary subjects she was clear and incisive and her opinions always carried weight. She had also a special capacity for condensing the facts and verbiage of government reports and stating in brief space the important matter they contained. Though little before the public eye, and never courting publicity, but rather avoiding it, she was sought out and honored by the greatest personages in her own country and was the only woman on whom has been conferred the "Order of Merit." It is said that she was always accessible to the workers in the institutions which she founded and always took the liveliest interest in them. Hardly any one of her countrywomen has done work more effective for good or has left behind her a choicer memory.

Medical News

CALIFORNIA

Fighting Tuberculosis in Schools.—The superintendent of the Oakland schools has inaugurated a system of breathing exercises among the pupils with the view of increasing their lung expansion. Some remarkable results have been attained. Not only has the general average of the lung expansion of the pupils been increased but in some instances the expansion has reached six to seven inches. It is found that the girls respond more readily to these exercises than the boys and that the white children show far better results than the Chinese, Japanese or negroes.

Hospitals.—The contract has been let for the construction of five new ward buildings, an administration building and nurses' home for the new public hospital at San Francisco. The cost of the work will be approximately \$220,000. The material used will be brick, marble and terra cotta.—Building has commenced on the hospital at Hanford.—The staff of the Berkeley Dispensary has been made up as follows: Drs. Frank W. Edmonds, Robert Hector, Frank Simpson, Fred H. Van Tassell, Thomas C. McCleave, Romilda Paroni, Wilbur A. Sawyer, Florence Sylvester, John U. Force, May H. Sampson, Edith S. Brownsill and E. B. Hoag.

Personal.—Dr. Anderson, San Francisco, has been made assistant surgeon by the Northwestern Pacific Railroad Company, stationed at the Bryan Bluff Receiving Hospital.—Dr. Frank R. Dray has been appointed chief medical officer of the German Hospital Association at San Francisco.—Dr. Howard W. Levensgood, Ocean Park, has been appointed professor of state medicine and hygiene in the College of Physi-

cians and Surgeons, University of Southern California.—Dr. E. W. Parsons has resigned from the Emergency Hospital, San Francisco, and will be succeeded by Dr. Fred H. Zumwalt.—Dr. James M. Gassaway, surgeon in charge of the United States Marine Hospital, San Francisco, was injured in a street car accident, sustaining fractures of the pelvis, one rib and one leg in two places.

FLORIDA

New Hospital.—The new Mission Hospital was recently opened at Pensacola. A staff of twenty-two of the leading physicians of Pensacola was appointed, with Dr. Juriah H. Pierpont as chairman of the medical board.

Enforcing Health Ordinances.—City Health Officer Charles E. Terry, Jacksonville, has invoked the assistance of the police in enforcing the city health ordinance relative to the protection of meat, fish, fruit and vegetables from flies and other insects. The dealers are required to protect these articles by screens.

Branch Laboratory.—The state board of health has opened a branch laboratory in Pensacola, and has placed in charge Dr. F. A. Brink, formerly of North Dakota. The establishment of the laboratory will materially aid the profession in that section of the state in their crusade against communicable diseases, especially hookworm and tuberculosis.

Appointment of Visiting Staff.—At the recent meeting of the Board of Commissioners of State Institutions at Tallahassee, on the recommendation of B. F. Whitner, superintendent of the Florida Hospital for the Insane, the following physicians were named on the visiting staff: Drs. Gerry R. Holden, Jacksonville; James H. Randolph, Chattahoochee; Clarence E. Hutchinson, Pensacola; Henry E. Palmer, Tallahassee, and Urban S. Bird, Tampa.

Crusade Against Malaria.—At the annual meeting of the State Medical Society, held in Jacksonville last April, a special committee was appointed to inaugurate a campaign throughout the state against malaria. This committee has issued an address to the people of the state stating that the first step in the campaign is to secure the cooperation of the public and that heretofore those interested in public health had not been supported. The committee in its address then says:

To accomplish this end, there will appear in the daily press of the state, a series of bulletins, issued at certain intervals, for the purpose of educating the public on the damage done to the state as a result of malaria, the extent to which the disease prevails, how the infection is carried from person to person, correcting the many false impressions concerning its transmission, showing how little decrease there has been in the disease during the past decade in this and other southern states, what has been accomplished in other parts of the world during the same period, as a result of a properly organized campaign, and finally, a summary of how it is possible to entirely eradicate the infection from our South, if the people generally will aid in every way they can.

The committee is composed of Drs. Graham E. Henson, E. VanHood and Edmund W. Warren. They have issued Bulletin 1, which has been published in the newspapers throughout the state, in which they state the situation in regard to malaria. They say that from two hundred to four hundred lives are offered as sacrifices to malaria in the state every year, equal to an annual cash loss of \$800,000, estimating the value of each life at \$2,000. In addition to that, the loss in wages, cost of attendance, drugs, etc., amounts to \$400,000 more.

ILLINOIS

Evanston's Health Record.—Evanston claims to be the healthiest city in the state, the death rate for the past year being reported as only nine per 1,000 of population.

New Hospital.—Plans for the new \$50,000 Methodist Hospital at Peoria have been completed and bids asked for. The plans provide for a four-story building in the renaissance style, 70 by 80 feet. The kitchen will be placed on the top floor.

School Boards and Medical Inspection.—At Rockford, Corporation Counsel Rew has rendered an opinion that inspection of school children must be done under the supervision of the city health department instead of the school board, and that the board of education cannot legally provide for medical inspection. It is said that State Attorney-General Stead and State Superintendent Blair hold the same opinion.

Chicago

New Emergency Wards.—Since the abandonment of the old Harrison Street Emergency Hospital, two rooms have been fitted up in the Harrison Street Police Station for emergency hospital purposes, in charge of Drs. Charles D. and Clarence

H. Wall. As many as ten to fifteen minor surgical cases have been cared for each day since.

Personal.—Dr. and Mrs. Isaac A. Abt sail for Europe August 20 to be gone until November.—Dr. George Sultan has become a candidate for county commissioner of Cook County. His candidacy is endorsed by many leading physicians.—Dr. Milton J. Rosenau, professor of pathology in Harvard University Medical School, is to deliver the Harris Lectures for 1912 at Northwestern University. These lectures were established by the gift of Mr. Norman W. Harris.—Dr. B. Georgas is convalescing from appendicitis at Lincoln Hospital.—Dr. B. C. Corbus has gone to Berlin to investigate the new Ehrlich treatment.

Funds for Tuberculosis Institute.—The Chicago Tuberculosis Institute is endeavoring to raise a midsummer fund of \$2,500 with which to support the work until fall. The eight free tuberculosis dispensaries are handling from twenty to sixty patients a day. Every month about 240 new cases are examined, and the eleven nurses are making nearly 1,700 visits a month in homes of the patients. In addition three of the nurses devote a portion of their time to three open air schools for anemic children maintained at the Libby School, Penn School and Lake View High School. There are 35 children in each school.

Health Conditions.—For the first time during the summer the weekly death rate in the city was below that of last year, for the week ending August 13 the rate being 13.6 per 1,000 as against 13.9. Diphtheria was unusually prevalent, there being 79 new cases as against 49 for the corresponding week of last year, with 8 deaths as against 4 last year. The health commissioner, in addressing residents of the Twenty-ninth Ward, where sanitary conditions have been particularly bad, said "there is no such thing as a public standard until there is a proper standard of private living." Clean up day in the city was arranged for Tuesday, August 16, and was well observed.

IOWA

New Wing to University Hospital.—The state has purchased the Asa Moler property east of the present hospital site and will erect a new wing to the University Hospital.

Personal.—Dr. Campbell Howard, Montreal, Que., has accepted the chair of internal medicine at Iowa State University, Des Moines, and Dr. Erwin Schenck, Des Moines, has been made professor of skin diseases.

Visiting Nurses' Association.—At Burlington the work of the visiting nurses' association has been organized and Miss Augusta M. Jones, Moline, Ill., will have charge. Among those directing the work will be Drs. John C. Fleming and George B. Little.

Poliomyelitis.—About fifty cases of poliomyelitis have been reported from Mason City. Isolated cases have also been reported from other places. The State Board of Health held a conference August 17 to consider the best way of dealing with the disease.

Infant Mortality.—According to a statement of Dr. G. H. Sumner, secretary of the State Board of Health, one-third of the babies in Iowa under one year of age have died since the hot weather set in. The deaths are due principally to cholera infantum, infantile paralysis, poor milk and improper care. Cholera infantum and infantile paralysis have become so serious that the board has called a special convention of physicians throughout the state to discuss means of handling the situation.

KANSAS

Personal.—Dr. Seth A. Hammel, Topeka, has been appointed first lieutenant in the medical department of the Kansas National Guard, in the place of Dr. J. W. Graybill, Wichita.

Kansas City Health Board Changed.—Kansas City has passed an ordinance abolishing the old board of health and establishing a health department under a health commissioner, who is to be a graduate physician skilled in laboratory work. There will be in addition to the commissioner, three field men, a laboratory assistant and a clerk. It is hoped by this method to lessen the expense and at the same time attain a more efficient administration of health matters.

State Board on Poliomyelitis.—The July number of the *Bulletin of the Kansas State Board of Health*, aside from the table of vital statistics, is almost wholly taken up with an article on epidemic anterior poliomyelitis, a disease which prevails to some extent in Kansas. In addition to the symptomatology, course and pathology of the disease, the history of the present epidemic is given. The bulletin is illustrated

with micro-photographs of sections of the spinal cord taken from fatal cases, and the whole bulletin makes a valuable contribution to the subject of infantile paralysis. The health board has issued to the people of Kansas a set of rules looking to the prophylaxis of poliomyelitis among the children.

MARYLAND

State Society Meeting.—The semi-annual meeting of the Medical and Chirurgical Faculty will be held at Annapolis, September 12-14. The Anne Arundel County Medical Society has appointed a committee to prepare for their entertainment. A joint meeting with the Maryland Psychiatric Society will be held. The membership of the state society now is 1,069. The publication committee estimates that the saving during the past year by the publication of the *Bulletin* has been about \$700.

Baltimore

Report of Insane Hospital.—In the sixty-seventh annual report of Mount Hope Retreat, Dr. Charles G. Hill, physician-in-chief, gives the total number of patients treated last year as 985; 257 were discharged and 63 died. Dr. Hill discusses interestingly the causes and circumstances surrounding the insane.

Death from Rabies.—A child five years old died from rabies at Mercy Hospital, August 10. This is the fourth death of those treated at the Pasteur Institute in the eighteen years of its existence. The child was bitten with eight others May 23 last. There were two bites in her cheek. The other cases were all treated and are doing well.

Druggists and Soothing Syrups.—It is said that at the meeting of the Baltimore Retail Druggists' Association, to be held in September, the druggists will decide not to handle soothing syrups now fed to children by mothers. There is no law prohibiting their sale, unless they contain laudanum, and all do not contain it. Following the action of the government, many cities have already taken decided action in the matter.

Personal.—Dr. Alfred Whitehead is in the Berkshire Hills, Mass.—Dr. William S. Halstead has returned from Europe.—Dr. Arthur P. Herring, secretary of the Lunacy Commission, is reported to have narrowly escaped drowning in the natatorium of the Hotel Chamberlin at Old Point Comfort, Va., August 7.—Dr. Andrew H. Whitridge was operated on for appendicitis early last week at Interlaken, Switzerland.—Dr. Howard W. Jones has been sued for \$10,000 damages for the death of a boy, alleged to be due to injury inflicted by the doctor's automobile.

MASSACHUSETTS

Typhoid in Worcester.—Twelve cases of typhoid fever have been reported in Worcester. It is said that all of the cases have been traced to the use of milk distributed by one dealer.

Open-Air School for Children.—The gratifying experience of Boston's open-air school conducted last winter for tuberculous and anemic children has led the authorities to extend this plan for the coming winter.

Infantile Paralysis.—At Springfield, in view of the increasing death-rate from infantile paralysis, the local board of health has increased the quarantine period from two to four weeks. The disease has attacked a number of adults, and one death of an adult has occurred.

Preventing Blindness.—Dr. Mark W. Richardson, secretary of the state board of health, has been sending to every physician of the state a vial of 1 per cent. nitrate of silver solution to be used for the prevention of ophthalmia neonatorum, and has issued a circular giving suggestions as to its use.

Governor Approves Work of Physicians.—At the annual dinner of the Massachusetts Medical Society, in Boston, Governor Draper addressed the physicians and said: "I believe there is no profession which is bringing forward so many innovations for the benefit of mankind as this old and honorable profession of yours. Medicine has made bigger strides and developed more than any other profession."

Unsanitary Condition of River.—Protest has been made by citizens against the unsanitary condition of the upper section of the Charles River, including the Lower Falls and Upper Falls districts of the Metropolitan Park district. Concerted action will be taken by the citizens of the towns along the river to ask the next legislature to clean out the river and prevent further pollution by mills and factories.

Medical Inspection of Schools.—The board of health of Boston has submitted to the mayor a plan of reorganization

of the corps of medical inspectors in the public schools. By this plan the board of medical inspectors will be reduced from eighty to forty and the salaries increased from \$200 to \$1,000. In addition ten physicians will devote their entire time to infectious diseases, and the salary to be paid them will be \$500 per year each.

Personal.—Dr. George D. Henderson has been appointed medical inspector at Holyoke. He will examine school pupils wishing to go to work.—Dr. Richard C. Cabot, Boston, was presented with a loving cup by the summer class at the Massachusetts General Hospital. Dr. and Mrs. Cabot entertained the class at their summer home at Cohasset.—Dr. William J. Brickley, Charlestown, has been given charge of the City Hospital relief station in Haymarket Square, Boston, to succeed Dr. Edwin L. Drowne.

New Child Labor Law.—The law passed by the last legislature providing that children between the ages of 14 and 16 must be inspected by a physician before going to work in factories, workshops or mercantile establishments went into effect August 1. The committee on medical inspection of the State Child Labor Committee has issued a statement calling the attention of the public to the new law. It is found that many minors in Massachusetts factories are in ill health and unfit to work.

MICHIGAN

Personal.—Dr. John H. Pettis, West Branch, has been appointed to a position in the State University at Ann Arbor.

New Emergency Hospital.—A new emergency hospital for contagious diseases will be erected at Flint, on the site of the present hospital, at a cost of \$2,500.

Gift of Sanitarium.—C. W. Post, Battle Creek, has given to the Traders' and Workers' Association at Battle Creek the Phelps Sanitarium building erected several years ago at a cost of \$400,000. It will be used for hospital purposes by the association.

Smallpox in Michigan.—Smallpox is prevalent in a number of places throughout the state at the present time. There has been one case reported from Mackinac Island and one or two suspected cases are being watched for developments. The disease is being taken care of by the local health authorities of the state, cooperating with the state board of health.

Work Against Tuberculosis.—The City of Kalamazoo has arranged to establish open-air schools for children with tuberculosis and for anemic pupils, who need plenty of fresh air.—Muskegon has begun a poster campaign against tuberculosis by placing on billboards in various parts of the city posters nine feet high pointing out the essentials for the prevention of tuberculosis. According to Secretary Murray of the State Board of Corrections and Charities a great deal of tuberculosis exists in the county infirmaries, jails and other public institutions, and the situation calls loudly for relief.

NEW YORK

De Peyster Home May Close.—This institution, located at Verbank, near Poughkeepsie, which has been in existence for nearly a century, may be forced to close for want of funds unless money is forthcoming at once. There are about one hundred invalid children in the home at present.

Health Field Day at Rochester.—Rochester's health field day, participated in by the military companies, civic and athletic societies and the school children of the city, and generously supported by the public, was a great success and resulted in a fund of \$5,000 for the benefit of the children's free dispensary.

Personal.—Dr. A. T. Bull, the oldest practitioner in Buffalo, hale and hearty until a few weeks ago, at 85 has been made an honorary member of the Erie County Medical Society and an honorary life member of the Buffalo Academy of Medicine. Two weeks ago, however, in attempting to board a street car he was thrown to the street and seriously injured. He is still in a critical condition and may not recover.

New York City

Coal Lands for Hospital.—By the will of Normal I. Rees St. Luke's Hospital will receive about 6,000 acres of coal and iron lands in Virginia and West Virginia.

Women Want Internships.—Dr. Maud Glasgow has initiated a movement to get women admitted as interns into the larger hospitals of New York. There are said to be only two smaller hospitals in Greater New York where women can be admitted as interns.

German Hospital Needs Money.—The addition to the German Hospital of Brooklyn which was so urgently needed has been begun without provision having been made to defray the entire cost, so the board of trustees has appealed to the general public for funds with which to carry on the work.

Another Move by Osteopaths.—The osteopaths are still struggling for recognition by the health board. A motion has just been argued before the Supreme Court of Brooklyn for an injunction to restrain the board of health from enforcing Section 163A of the Sanitary Code, which provides that no transit permit shall be granted for the burial of a person who has been treated by an osteopath until the body has been examined by a regular physician. Justice Putnam reserved his decision.

Milk Dealers Willing to Cooperate.—The board of health has placed its ban on all pasteurized milk in bulk as food for infants unless it is boiled and Dr. Lederle has suggested that dealers and dairymen cooperate with the department in producing milk of definite grades suitable for young children. Dealers have expressed their willingness to do what they can and are considering plans which they will submit to the board of health. Of the 1,600,000 quarts of milk received daily in this city only about 2 per cent. is certified or guaranteed. The aim of the department is to get a sufficiently good quality of milk for babies at a reasonable price, such as is sold in many European cities.

Harvey Lecture Program.—The Harvey Society elected the following officers for the year 1910-1911: President, Dr. Simon Flexner; vice-president, Dr. John Howland; treasurer, Dr. Edward K. Dunham; secretary, Dr. Haven Emerson; council, Drs. Graham Lusk, S. J. Meltzer and James Ewing. The following program for the next series of lectures has been arranged:

October 15.—Prof. Dr. H. Chiari of Strassburg, Germany, on "Die Bedeutung der pathologischen Autopsie und sonstiger pathologisch-anatomischen Untersuchungen."

November 12.—Prof. W. E. Castle of Harvard University, on "Unit Characters in Heredity."

December 10.—Prof. Harvey Cushing of Johns Hopkins University, on "Certain Clinical Aspects of Dyspituitarism."

January 14.—Prof. Arthur R. Cushny of the University of London.

February 4.—Dr. Thomas B. Osborne of the Connecticut Agricultural Experiment Station, New Haven, on "The Chemistry of the Proteins."

February 25.—Prof. Jacques Loeb of the Rockefeller Institute for Medical Research.

March 18.—Prof. H. Gideon Wells of the University of Chicago.

These lectures are open to the public and are given on Saturday evenings at the New York Academy of Medicine.

NORTH CAROLINA

Free Dispensary.—A new free dispensary at Asheville was opened August 15, in charge of Drs. Frazer, Ringer and Herbert. The dispensary was founded by the Associated Charities.

Pure Water.—Sixty-three municipalities of this state have public water supplies which have collectively received during 1,486 examinations in the state laboratory of hygiene with the net result of finding only 5 per cent. of contaminated water. Practically all of those found deficient have, under direction of the State Board of Health, corrected the defective water service.

State Health Secretary on Vaccination.—The annual report of the secretary of the State Board of Health in the June *Bulletin* of the board discusses the question of quarantine for smallpox. The secretary approves of the action of Minnesota and South Carolina in abolishing quarantine, and says that if it was generally known that there would be no quarantine nearly everybody would be vaccinated. He then says that the minority would consist of two classes of people:

The first class are those whose sense of responsibility for community health is such that they are more influenced by the anticipated slight personal discomfort of a sore arm than they are influenced by considerations of the public weal. The second class are our esteemed friends who do not believe in the protective power of vaccination. To these science is dumb and experience is a liar. And yet to protect these two classes we quarantine. To protect them when they alone last year spread the disease all over our fair state, put the state to an expense of \$40,000 to \$50,000! Do these civic irresponsibles deserve an altogether unnecessary expenditure of \$50,000 by those who have discharged their civic obligation in the matter of smallpox? My answer is: No.

Free Diphtheria Antitoxin.—For more than a year past the State Board of Health has provided diphtheria antitoxin at actual cost to all indigents who reside in counties applying for the same—the cost eventually being borne by the counties themselves; forty-nine counties and thirteen cities during the past year availed themselves of the privileges of the reduced

cost in diphtheria antitoxin. There is a move now on foot to secure such legislation from the coming legislature as shall enable the state to establish a plant for the production of its own antitoxin.

Judgment Against Physician.—In the Superior Court at Wilmington last week judgment was obtained against Dr. Lionel H. Love, formerly of that city, but for the three years past a resident of Monterey, Cal., in the sum of \$5,000 for damages in an action brought by a former patient whose dislocated and fractured arm was treated by Dr. Love some ten years ago. Dr. Love admitted the arm was out of joint but insisted the plaintiff would not consent to an anesthetic, without which, owing to local conditions at the time, it was impossible to make a correct diagnosis. Appeal was taken to the Supreme Court.

Personal.—Dr. Robert L. Gibbon, Charlotte, is convalescing from a severe attack of typhoid fever.—Dr. O. L. Holler, Taylorville, while driving to a patient during a severe storm August 1, was struck by a falling tree, sustaining a fracture of the skull. Unconsciousness supervened immediately, trephining was done by Dr. H. F. Long of Statesville, and later Dr. Holler regained consciousness with a fair prospect of recovery.—Dr. J. S. Lafferty, Charlotte, is doing post-graduate work in Berlin.—Dr. J. Herbert Mease of Canton has been nominated by the democrats for representative in the state legislature for the ensuing term of two years.

Hospital Investigation.—The State Board of Internal Improvements spent several days in session at Greensboro last week hearing evidence relating to the charges preferred against Dr. J. R. Brooks, superintendent of the State Sanatorium for Tuberculosis at Montrose, and the trustees of the institution, by Dr. John Roy Williams of Greensboro. The trustees include three well known physicians besides six other prominent citizens. The State Sanatorium was opened early in 1908 when the accommodations were probably insufficient and the exhaustion of the legislative appropriation prevented the completing of the full equipment of the sanatorium. The findings were wholly at variance with the charges made, and the trustees and Dr. Brooks were vindicated fully in the report to the governor.

Examination of Troops for Hookworm.—Dr. John T. Ferrall, working under the joint auspices of the State Board of Health and the Rockefeller Commission as special assistant, has just completed the examination of the members of the state guard at the annual encampment. As a result it appears that the Second Guard Regiment (from eastern or coastal Carolina), showed 57 per cent. of infection, and the First Regiment (from the western or mountain section), 37 per cent. The examination of the Third Regiment (central Carolina), was not so complete as were those of the other two regiments, but apparently it showed about 40 per cent. of its men infected with hookworm. Much interest is being manifested by physicians of the state in diagnosing the disease, a report from the state laboratory of hygiene at Raleigh showing an average of twenty-five specimens of feces arriving daily for microscopic study and report.

PENNSYLVANIA

Personal.—Dr. B. H. Detwiler of Williamsport, is seriously ill with paralysis. His whole right side is affected.

Infantile Paralysis.—Two deaths from and three new cases of infantile paralysis were reported to the health authorities at South Bethlehem, August 8.

State Sanatorium Bids.—Bids for the construction of the buildings of the State Tuberculosis Sanatorium to be erected at Cresson show that the work will cost about \$250,000.

Typhoid at Wilkes-Barre.—On August 8 seven new cases of typhoid fever were reported in Wilkes-Barre, making a total of 50. The state health authorities have been asked to make a thorough investigation.

Rittersville Investigation.—The report of Mr. Lindley Johnson, the consulting architect retained last May by the State Board of Public Grounds and Buildings to investigate the work of the State Homeopathic Hospital for the Insane at Rittersville, was made public by Governor Stuart on August 12. The work was begun nine years ago and not one of the buildings has been completed. Appropriations by various legislatures for this work total \$1,703,750, and contracts already let for the work amount to \$1,482,445.83. To complete the buildings will require \$349,000. The balance in the

state treasury is \$272,781.40, so that an additional appropriation of \$76,219.60 will be required to finish the work, according to Mr. Johnson's ideas. He says that the work is well executed and that the hospital can be put in condition to receive some patients within four months, though at least a year will be required before the institution can be completed. He also reports that many of the buildings have suffered from exposure to the weather in an incompleting state. Many walls have been disfigured and much plastering ruined, but the buildings have not been structurally weakened.

Philadelphia

Personal.—Dr. Louis J. Burns sailed for Europe August 11 and Dr. George E. de Schweinitz August 13.—Dr. Edward P. Davis sailed August 10 to attend the International Gynecologic Congress in St. Petersburg, to which he is a delegate from the American Gynecological Society and the Jefferson Medical College.

Unlicensed Druggists Arraigned.—In the crusade against unlicensed drug-stores and the compounding of prescriptions by "quack" pharmacists, the State Pharmaceutical Board had four druggists of "Little Italy" arraigned before Magistrate Beaton August 12. In each case the druggists who violated the law were held under \$600 bail for court.

Typhoid Increase Due to Carelessness.—Investigation of typhoid fever cases reported in the two weeks ending August 13, showed that 72 per cent. were men between ages of 17 and 32, and 28 per cent. were women. Chief Vogelson of the Bureau of Health said that the history of many of the cases showed that young men on boating trips had drunk raw river water.

Hospital for Midvale Steel Works.—Plans have been prepared for a two-story fire-proof hospital building, 54 by 80 feet, containing emergency wards, dispensary and quarters for a doctor. At present, a physician makes daily visits to the Midvale Steel Works, but because of frequent accidents in the shops, it has been found necessary to have a doctor in constant attendance.

Maker of Soothing Syrup Arrested.—Following the resolutions made by the Retail Druggists' Association to stamp out the indiscriminate sale of doped soothing syrups, a warrant was sworn out before Magistrate Beaton, by Dr. Christopher Koch, vice-president of the State Pharmaceutical Board, for the arrest of Mrs. M. M. Harvey, manufacturer of "Mother's Comfort," a medicine which has been found to contain one-third of a grain of morphin to the ounce.

Free Dental Treatment.—A dental clinic is to be established in the city hall, under the direction of the Department of Health and Charities. An appropriation of \$3,000 for this purpose was made by councils several months ago. The committee to have charge of the dental dispensary is composed of P. B. McCullough, chairman, and Drs. W. A. Jaquette, Edward C. Kirk, J. J. Burke and Charles B. Schupack. One hundred dentists have volunteered their services, and rooms will be fitted up with all the modern appliances. It has been estimated that 80 per cent. of the public and parochial school children are in need of dental treatment.

War Against Doped Soft Drinks.—Up to August 13. 60 warrants had been sworn out by Special Agent H. P. Cassidy, of the State Dairy and Food Department, for the arrest of bottlers, who are charged with putting harmful substances into bottled soft drinks. Fourteen were ordered to appear for a hearing before Magistrate Beaton August 16. Some have already been convicted of adulterating their products and have paid heavy fines. Samples were taken of the cheap varieties of soda by Agent Cassidy and were analyzed by Prof. Charles H. Lawall, chemist for the State Dairy and Food Department, and were found to contain saccharin and soap bark. Children are the principal purchasers of the cheap drinks and it is thought that much of the illness among children in the tenement district is due to this fact.

Space on Recreation Piers to be Increased.—As a result of an inspection tour made on August 9 by Dr. Neff, Chief Eisenbower, of the Bureau of City Property, and Select Councilman Ryan, the space on the Chestnut and Race Street piers will be greatly increased. The report of the work on the Chestnut Street pier is as follows: Daily attendance, sick infants, 20; well infants, 24; older children, 36. Total attendance of children, 80. The attendance at the Race Street pier was equally good. Large quantities of medicines and modified milk have been distributed since the centers were opened ten days ago. Figures relative to the work being done in connection with the campaign for the reduction of

infant mortality, show that during the week ending August 13, 19 nurses were engaged. They made a total of 1,374 visits and assisted in the care of 224 infants.

SOUTH CAROLINA

Personal.—Dr. Charles Speissegger, Jr., Charlestown, has received his commission as army surgeon with the rank of first lieutenant.

Pasteur Institute.—The board of health of Charlestown has opened a Pasteur institute for the treatment of rabies. It will be in charge of Drs. John M. Green and George M. Mood.

New City Hospital.—A charter has been secured and building will be begun immediately on a new city hospital at Gaffney. The capital stock is \$10,000. Dr. R. T. Ferguson is secretary-treasurer of the organization.

Medical Society Meetings.—At a meeting of the Palmetto Medical Association, composed of colored physicians of the state, the following officers were elected: President, Dr. H. C. Hardy, Spartanburg; vice-president, Dr. L. S. Edwards; secretary, Dr. Issac N. Macon, Rock Hill, and treasurer, Dr. J. S. Allen, Chester. Lancaster County Medical Association was organized at Lancaster recently and the following officers elected: President, Dr. Thomas J. Strait, and Dr. William F. Laney, secretary, both of Lancaster.

VERMONT

Personal.—Dr. Richard G. Eaton, Wakefield, Mass., has been appointed by the trustees of the Brattleboro Retreat second assistant physician, to succeed Dr. Park R. Hoyt, recently resigned.

Health Officers Meet.—The twelfth annual school of instruction for health officers was in session at Montpelier for four days, beginning August 1. Dr. George M. Kober, Georgetown University, Washington, D. C.; Dr. Henry A. Wood, Waltham, Mass., and Dr. Livingston Ferrand, New York, secretary of the National Association for the Study and Prevention of Tuberculosis, were the guests of the meeting. State's Attorney H. B. Shaw, Burlington, read a paper on "Legal Points in Health Work" and then answered legal questions raised by the health officers. He gives it as his opinion that the state board of health has no power to give to the health officer of a city or town the right to act in an adjoining town or city where a health officer has been appointed. He also ruled that complaints of nuisances must be made to the local health officer and not to one in an adjoining town or city. The proposition for a national department of health was endorsed.

VIRGINIA

Hookworm Examinations.—Dr. Roscoe C. Carnel, representative of the Virginia Board of Health, has been spending some time in Suffolk, cooperating with the physicians in that place in the study of hookworm cases.

School Inspection and Sanitation.—Medical inspection of the school children of the Norfolk public schools will be inaugurated for the coming term. The common drinking cup has been abolished and sanitary drinking fountains will be installed in all the schools.

New College Board.—In the reorganization of the University College of Medicine, Richmond, all the medical representatives of the board of trustees resigned and the new board is made up of laymen, except Dr. John W. Dunn, secretary. Dr. Stuart McGuire was elected president of the faculty.

Society Organized.—More than fifty physicians, representing the counties of Warren, Frederick, Clarke, Rockingham and Shenandoah, met at the Memorial Hospital in Winchester, August 10, and organized the Shenandoah Valley Medical Society. Dr. Durus D. Carter, Woodstock, was elected president and Dr. Cox, Winchester, secretary-treasurer. The organization will meet quarterly. Dr. Stuart McGuire, Richmond, was chosen counselor in the State Medical Society.

Work Against Tuberculosis.—The tuberculosis hospital at Petersburg, the first to be established in the state, is to enlarge and extend the sphere of its usefulness. The Hill Crest Settlement has purchased the farm on the southern border of the city, containing twenty acres and a dwelling house of ten rooms. The capacity of the institution will be enlarged. Realizing the necessity of work among negroes in order to make effective the fight against tuberculosis, it has been determined to organize leagues among teachers and students in the colored schools in the state. This work will be done under the direction of the State Antituberculosis Asso-

ciation, which recently held a meeting in the office of the state health department, Richmond. Dr. Charles P. Wertenbaker, United States Public Health and Marine-Hospital Service, was detailed by the surgeon-general to attend this meeting. Dr. William F. Drewry, Petersburg, was elected chairman of the committee. The colored people of the state are awakening to the necessity of combating the disease and are taking interest in the work of the colored antituberculosis league of Virginia. The first meeting of the league was held at Hampton, August 11, and a campaign along lines suggested by the state health department will be carried on among colored people in every part of the state. The seaside camp at Cape Henry, under the direction of the Norfolk Antituberculosis League, which takes care of children whose parents have died from tuberculosis, reports a very successful season. The camp opened June 12 and will remain open until September 1. The new tuberculosis camp on the city farm, Richmond, is completed and was opened August 15. There will be no resident physician, but Dr. Giles B. Cook will act as medical examiner.

GENERAL NEWS

Fighting Tuberculosis in the Philippines.—Hon. Jacob M. Dickinson, secretary of war, who has been visiting the Philippine Islands, assisted at Manila in the organization of a national society to fight tuberculosis. The disease has been making great inroads among the Filipinos.

International Red Cross Conference.—The ninth international conference of the Red Cross will be held in Washington, D. C., in May, 1912. Red Cross endowment fund committees of prominent men have recently been appointed in Chicago, St. Louis, Cincinnati and Washington by President Taft, and effort will be made to raise a fund of \$2,000,000 for the American Red Cross.

International Epilepsy Congress.—An international association for a systematic study of epilepsy and care and treatment of epileptics was organized at Budapest last year, and the first general meeting is to be held at Berlin Oct. 4 to 7, 1910. Prof. A. Tamburini of Rome and Prof. J. Donath of Budapest are, respectively, the president and the secretary of the association. Professor Veith will discuss the criminality of epileptics and a number of statistical works will be presented. The transactions will appear in the journal *Epilepsia*.

Health and Mortality in the Canal Zone.—The report of the Department of Sanitation of the Canal Zone for the month of May compares the mortality among the employees for the past four years. It shows that the number of deaths among the 39,000 employees in 1907 was 98, while among the 52,800 employees in 1910 it was only 34. The death rate per thousand during May among the white employees during American control was, 1907, 18.34; 1908, 14.59; 1909, 14.11; 1910, 6.98, and among the black employees during the same month, 1907, 34.48; 1908, 8.72; 1909, 7.87; 1910, 6.98. The average number of employees constantly sick per 1,000 in hospitals, sick camps and quarters, is, white, 46.48; colored, 15.80.

Mississippi Valley Meeting.—The annual meeting of the Mississippi Valley Medical Association will be held this year at Detroit, September 13, 14 and 15. The headquarters will be at the Hotel Pontchartrain. Dr. Frank P. Norbury, Hospital, Ill., is president; Dr. Henry Enos Tuley, Louisville, Ky., secretary, and Dr. Henry O. Walker, Detroit, chairman of the entertainment committee. A preliminary program has been issued, which may be obtained from the secretary on request.

Cholera May Prevent Medical Meeting.—The meeting of the International Gynecologic Congress, which was to be held in St. Petersburg in September, may not convene in that city on account of the epidemic of cholera prevailing there. Dr. Charles A. L. Reed, Cincinnati, president of the American committee and government delegate to the meeting, has cabled the Russian committee that if the meeting cannot be held there the American profession will welcome the organization to this country. The meeting of 1908, which was to be held in St. Petersburg, was deferred for the same reason.

Tuberculosis in Prisons.—Through the investigation of the National Association for the Study and Prevention of Tuberculosis, as set forth in a bulletin recently issued, there are 12,000 tuberculous prisoners in state, federal and local prisons and jails in the United States, or an average of 15 per cent. of the prison population. Only twenty-one prisons in fifteen states and territories have provided special places for the treatment of tuberculous prisoners. These institutions can accommodate only 800 patients. In three-fourths of the

larger prisons and jails no provision is made for isolating these patients. New York and Massachusetts are the only states where any systematic attempt has been made to transfer tuberculous prisoners to one central station. Tuberculosis is also exceedingly prevalent in the prisons of the Philippine Islands, and the largest tuberculosis hospital is in Manila where accommodation for 200 tuberculous prisoners is provided. The Clinton Prison Hospital in New York provides for 150. The 100,000 prisoners annually discharged from jails and prisoners, 15 per cent. of whom are tuberculous, present a serious problem in the distribution of tuberculosis.

FOREIGN

New Large Public Hospital at St. Petersburg.—The cornerstone of the Peter the Great Hospital was laid at St. Petersburg last month. It is to be the largest hospital in Russia, with thirty-seven separate buildings, and is expected to cost over \$10,000,000.

Personal.—The Astley Cooper prize has been awarded by the Guy's Hospital School to Professor E. Starling, F.R.S. At the meeting of the Berlin Academy of Sciences on June 30, commemorative addresses were made on Friedrich Kohlrausch, by Professor Rubens; on Hans Landolt, by Professor van't Hoff, and on Robert Koch, by Professor Rubner.

Russian Cholera Epidemic.—The cholera in Russia continues to spread, particularly in St. Petersburg and in the southern mining districts, and is approaching the proportions of the epidemic of 1908. Figures of the central sanitary bureau show that in the week ending July 30 there were 15,244 cases of cholera and 6,944 deaths. The government has decided to send to the mining regions a special commission to study the situation, empowered to organize sanitary preventive work. Industrial conditions are seriously handicapped in the afflicted regions.

Deaths in the Profession Abroad.—Besides those mentioned elsewhere the profession has lost the following eminent medical men: Larra y Cerezo, M.D., of Madrid, a high military medical officer and president of the Medical Press Association of Spain.—J. Grünfeld, M.D., of Vienna, prominent in syphilology and a pioneer in the field of endoscopy. He was 70 years old.—H. Berestnew, M.D., of Moscow, one of the leading bacteriologists of Russia.—George Herbert Rowe, M.R.C.S., Leeds, trustee and senior surgeon of the Leeds Dispensary, aged 53.—Claude Muirhead, M.D., F.R.C.P., consulting physician to the Royal Infirmary; died at Edinburgh June 22, aged 75.—Dr. G. B. Halford, late professor of physiology in the Melbourne University at Melbourne, Australia, aged 86.

MANILA LETTER

(From Our Regular Correspondent)

MANILA, June 21, 1910.

Medical Surveys of Native Towns

The medical survey party has returned from one of the northern provinces where it has been making investigations. It has been planned to send out at least one of these survey parties each year. They are arranged by the Bureau of Health, the Philippine Medical School and the Bureau of Science and are usually sent out during the vacation period of the medical school. Under a director the survey party goes to a typical native town of a district or province and with the aid of the presidency, the local head of the government, establishes a dispensary and makes a medical investigation of the town. The object is to inquire into the sanitary conditions of the inhabitants, the water supply and sewage disposal, to determine what contagious diseases, if any, are present and to what extent, to find what diseases are most prevalent—special attention being given to smallpox, plague, cholera, typhoid and dysentery—and to look into the midwife practice and infant mortality. Some difficulty is often encountered in overcoming the natural reserve and suspicion of the inhabitants. On this account locating the various people who are sick and inquiring into their mode of living often becomes quite a problem. The inhabitants will not always come to the free dispensary of their own accord until they have looked the intruders over and satisfied themselves of their purpose. In addition many cases of serious illness are likely to go unnoticed even after the best of relations have been established between the doctors and the natives. To overcome these difficulties, a happy plan was put into practice last year. This consisted in the taking of a complete

civil census of the town as the first part of the program. After the dispensary, laboratory and living quarters were established a house-to-house canvass was made. Thus the survey party soon became acquainted with the people and nearly all the cases of serious illness as well as insanitary homes, etc., were early located.

At Taytay last year a complete medical and geographic survey, as well as an anthropologic study of the people were made. The whole is published in a recent number of the *Philippine Journal of Science*. These surveys serve at least three purposes: They add to our knowledge of the variety, severity and extent of tropical diseases in the Orient and particularly in the Philippines. They materially aid the Bureau of Health in determining the sanitary condition of the average town of the various provinces of the Philippines, the geographic distribution of the rare diseases and of the more common epidemic diseases. The members of the parties become intimately acquainted with the Filipinos and are thus better able to carry into effect from time to time their program of sanitation; finally the Philippine Medical School is kept in close touch with the practical side of medical questions as they appear in the islands and it is enabled to vary the curriculum accordingly.

Polished Rice and Beriberi

In the Philippines in all specifications for commissary stores where rice is required for either the Army or Navy unpolished rice is specified. Polished rice is no longer used as a diet in either the Army, the Navy or in the public institutions of the islands. The supposed relation of polished rice, as a diet, to the development of beriberi is the direct cause of this ban. In so far as statistics are available and reliable, it would seem that since the introduction of improved rice-milling machinery into the Philippines the amount of beriberi among the natives has increased. Of course due allowance must be made in these considerations for a great number of cases reported as beriberi which are, to say the least, of a doubtful diagnosis. Since beriberi has been so much in the limelight of recent years in the Orient, it would hardly be an exaggeration to say that there has been a tendency to include various nervous disturbances under the heading of beriberi which in reality should have been classed as something else. In spite of this, a number of competent medical men both in the Philippines and in other parts of the Orient have observed an increase in the number of cases of this disease since polished rice has supplanted the hand-milled rice as the staple article of diet. In many sections the natives have early shown a preference for polished rice. It is rather noteworthy also that beriberi is decidedly more frequent among that class of natives whose staple and principal article of food is polished rice, and that in those remote regions where the Filipino still uses the unpolished rice, although rice is the principal article of diet, beriberi is relatively rare. These observations go hand in hand with the observations of Dr. de Haan that, in Netherlands India, it has been found beriberi could be kept very much in abeyance by adding to the white rice diet a form of green pea which is called "*katchung idj-ju*" and is said to be rich in phosphorus, as well as with the results of the experiments of Dr. Frazier and Dr. Stanton at the laboratory for medical research at Kuala Lumpur, Federated Malay States, who find "that fowls fed on highly polished rice suffer, within from 4 to 6 weeks, from a condition of inflammation of the nerves which closely resembles and may be identical with the condition of the nerves found in beriberi in human beings." All these things taken together suggest some indication of the etiology of the disease. It seems evident that beriberi is primarily a disease of nutrition and metabolism, and in local medical circles by many it is considered doubtful that beriberi is caused by an organism. Perhaps the most widely accepted view is that advocated by Dr. Frazier who points out that in a steady diet of polished rice, as is often the case here in the Orient, the individual fails to obtain sufficient nourishment for the peripheral nerves. He showed that the unpolished rice grain contains beneath the skin or pericarp a layer of cells rich in fat and phosphorus and that the central portion of the rice grain consists entirely of pure starch. In polished rice the outer fat-containing layer has been polished away. Rice prepared in the ordinary native fashion by hand milling contains a large amount of these oil-bearing layers. It is, moreover, the experience of the Bureau of Health of the Philippine Islands that a little meat or even the rice polishings mixed with a diet of white rice will lead to an improvement of beriberi patients in the early stage.

Peculiar Case of Helminthiasis

Last year a young woman very much emaciated generally but with a large protruding abdomen very much like the pot-bellied appearance of the native Filipino pig, came to the Philippine Medical School for treatment. For a long time she had been looked on with suspicion by the inhabitants of the town; it was considered that some curse was cast upon her by the Great Evil Spirit or some of the other numerous evil spirits. Consequently, she came very much into disrepute. According to one view it was thought that she had been loose in her morals and that for punishment she could not give birth to the child but must carry it indefinitely or until the spirits were appeased. After treatment by the American physicians she was delivered of 11 pounds of worms, regained her virtue and soon became a well woman.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Aug. 6, 1910.

Infant and Child Mortality

The local government board has issued a report prepared by its chief health officer, Dr. Newsholme, on infant and child mortality in England and Wales. This is the first systematic attempt to investigate the localization and extent and incidentally the causes and effects of a condition regarded as a blot on our civilization. In the last four years there has been a wide-spread awakening to the national importance of child mortality and a largely successful endeavor to diminish it. The object of the present report is threefold: to determine whether the reduction of infantile mortality implies any untoward influence on the health of the survivors to later years; to indicate the communities which are characterized by a continuing high rate of infant mortality, and to assess the different factors by which such mortality is brought about. An extraordinary difference is found in the infantile death-rates in different parts of the country, the mortality per 1,000 births in the first year of life varying from under 90 to over 150. In the first five years of life the mortality is also unequally distributed, being twice as high in some counties as others. Excessive infant mortality implies excessive mortality in later life. Counties having excessive infant death-rates have also excessive death-rates throughout the first twenty years of life, and counties having low infant death-rates have low total death-rates in this period. In the recent decline of infant mortality a higher standard of education, especially in its moral aspects, is considered an important factor. In 1906 and in 1908 national conferences on infant mortality were held and had a great educational influence. The Notification of Births Act of 1907 crystallized public opinion on the subject. Voluntary health associations as well as public health officials then concentrated on the problem of infant mortality and aided in the development of the "sanitary conscience." The main cause of excessive infant mortality is neglect of sanitation. For this the local health authorities are often responsible. So long as they permit excreta to be kept near houses in towns and allow streets to be unpaved domestic sanitation has not a fair chance. In many manufacturing districts, such as Durham, in which the death-rate of children is excessive, the laboring population is compelled, by the inaction of the local authorities, to live on a soil and in an atmosphere laden with filth, which contaminates food, clothing and person. Reports of this condition are constantly made by inspectors of the local government board, but they have no effect on the local authorities. Usually the health officer is a busy local physician who receives a small salary, which these authorities regard as a sop to keep him quiet, or he is unwilling to offend his patients by calling attention to their misdoings. In towns where the health officer devotes his whole time to the work he is more independent.

The British Pharmaceutical Conference

The forty-seventh annual meeting of the British Pharmaceutical Conference was opened at Cambridge on July 26. A large number of delegates attended from all parts of the United Kingdom. The presidential address was delivered by Mr. Francis Ransom, who emphasized the great need for pharmaceutical research and pointed out that the universities of this country are now offering increased facilities for the study of certain branches of science intimately connected with pharmacy. Looking over the vast amount of work done during the last 50 years by pharmacologists on the one hand and by chemists on the other, the question arose as to whether they might not have achieved more valuable results

if there had been a definite system of organization to bring together the two classes of investigators. He suggested that a joint committee should be appointed to consist of representatives of the British Pharmaceutical Conference and of the British Medical Association with a view to organizing medical research between physicians and pharmacists. This committee would be able to establish the value or worthlessness of any remedy. An investigation could be undertaken by the pharmacologists to determine its remedial value, by the physiologist to determine its action, by the chemist to ascertain its composition and by the pharmacist to determine a suitable preparation. Mr. Ransom also referred to the necessity for studying the cultivation of medicinal plants with the object of ascertaining under what condition the best results could be obtained. At present there was much diversity of opinion as to the cause of temporary variation in the quality of certain drugs, and this afforded scope for botanic investigation. Thus there was a remarkable divergence in the percentage of active principle in jalap of commerce; a similar divergence had been noted in belladonna root, some plants yielding thrice as much alkaloid as others. Again, it was generally thought that the value of many medicinal preparations was not entirely dependent on the alkaloids which they contained, but also on other constituents. This question opened up a wide field for research.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Aug. 5, 1910.

The Third International Congress of Educational Hygiene

The formal opening session of the third Congrès international d'hygiène scolaire was held on August 2 at the Sorbonne, under the honorary presidency of Professor Landouzy, dean of the Paris college of medicine. The congress was attended by 1,600 persons, most of whom were from the northern countries, especially Sweden, Norway, Denmark and England. The vacation season was both favorable and unfavorable. It brought to Paris a great number of foreign members, but many French members were kept away by attendance at other scientific meetings, as I mentioned in a previous letter (THE JOURNAL, July 23, 1910, p. 325). In his opening address, Dr. Landouzy took for his subject the rôle of the physician in educational hygiene. He showed how much this rôle has been enlarged since to-day on the school physician rest many duties, such as the sanitary supervision of the school, the prophylaxis of contagious diseases, the keeping of the sanitary records of the school building and of the individual pupils; the instruction of the teachers in hygiene, and the consideration of the programs, methods and the hours suitable for the various ages, the two sexes and for the various subjects of instruction. The great philosopher Descartes wrote almost prophetically in the seventeenth century: "Principally also, for the preservation of health, which is doubtless the first good thing, and the foundation of all other good things of this life, if it is possible to find anything which will make man wiser or more skilful than he has been hitherto, I believe that we must seek it in medicine."

The congress is divided into eleven sections, some of which are presided over by physicians and some by educators. The first section, that on school buildings and furniture, is presided over by Dr. J. A. Courmont, professor of hygiene in the Lyons college of medicine; the third, that on medical inspection of schools, by Dr. Le Gendre, physician of the hospitals of Paris; the fifth, that on the prophylaxis of contagious diseases, by Dr. Hutinel, clinical professor of children's diseases in the Paris college of medicine; the eighth section, that on the instruction of teachers in hygiene, by Dr. Pinard, professor in the Paris college of medicine; the eleventh section, that on the hygiene of the sight, the hearing, the mouth and the teeth, by Dr. Truc, professor of clinical ophthalmology at the Montpellier college of medicine. The other sections are concerned with the physical education, hygiene outside of schools (fresh-air schools, vacation colonies), hygiene among the teaching force, programs and methods of instruction in their relation to educational hygiene, special schools for abnormal children, etc.

Besides the work in sections, the congress has already held several general sessions. One of these sessions was devoted to the question of the standardization of the methods of the physical examination of pupils, on which a report was made by Dr. Méry, agrégé professor at the Paris college of medicine, and Dr. Dufetel, medical inspector of schools of the city of Paris, who recommend that the weight, the height

and the circumference of the thorax of pupils be measured in a uniform way, so that the results obtained by various observers may be compared to advantage. The general session devoted to the delicate question of the sexual education of children brought together a large attendance. Dr. Doléris, member of the Académie de médecine of Paris, in his paper especially emphasizes the necessity of organizing in the normal schools, special courses, taught by physicians, for the purpose of enabling teachers to give sexual instruction to their pupils.

The congress passed a resolution in favor of the adoption of the vertical handwriting and of the erection of bath-rooms and shower baths in primary schools. It also advocated dental inspection by specialists, each school semester, the offices of inspecting dentist and practicing dentist being distinct, and the family being allowed entire liberty in the choice of the practicing dentist. The congress also voted the adoption of the conclusions of the report of Dr. Cazalet, president of the Union des Sociétés de gymnastique de France, in regard to the necessity of rendering physical education compulsory in all educational establishments.

Personal

Dr. A. Gilbert, professor of therapeutics at the Paris college of medicine, has been recently appointed professor of clinical medicine to replace Dr. Dieulafoy. The council of the college unanimously proposed for the chair of therapeutics, thus made vacant, Dr. Marfan, *agrégé* and physician of the Paris hospitals. The new professor is known especially for his work on pediatrics. He has published a treatise on breast-feeding and artificial feeding, which has had great success.

At the Bordeaux college of medicine, Dr. Lagrange, *agrégé*, has been chosen professor of clinical ophthalmology in place of Dr. Badal. At the same college, Dr. Auché has been chosen professor of hygiene, replacing Dr. Layet. At the college of Nancy, Dr. Hoche, *agrégé*, has been chosen professor of pathologic anatomy.

Measures Adopted Against Cholera

The *Journal Officiel* has just published a decree, stating the sanitary measures to be taken for preventing the importation of cholera into France. Every person coming from a cholera-infected region who presents suspicious symptoms on arriving at the French frontier will be detained at the frontier station by a special commissioner and isolated. The following articles are prohibited from entering France by the land frontier: soiled clothing and bedding, rags (except baled rags, transported in bulk) and fruit and vegetables growing under the soil or on the surface of the soil. Every person giving lodging to a traveler who comes directly from infected regions, or has left such regions within less than eight days, is bound to report the fact to the mayor of the commune, or in Paris, to the prefect of police, within twenty-four hours. Every case suspected of being cholera must be immediately reported to the mayor's office, by the physician, the head of the family, the persons in charge of the patient or by those with whom he is lodging. Infractions of this decree are punishable by imprisonment of from fifteen days to three months, and by a fine of not more than \$100 (500 francs).

Yellow Fever

An English packet, the *Augustine*, bound from New York to Liverpool, was to have put in at Cherbourg, but several cases of yellow fever having broken out on board, the packet was obliged to put in at Havre, in order to be quarantined and put in sanitary condition.

Rioting by Pharmacists' Assistants

As I mentioned in one of my previous letters, the association of pharmacists' assistants obtained from the pharmacists, after long negotiations, the closing of the drug-stores at 9 o'clock, in all of the arrondissements of Paris, beginning August 1. But out of 1,500 of the drug-stores in Paris, four or five situated in the center, the special feature of whose business was to keep open all night, refused assent to this agreement, and continued open as in the past. To compel them to close, the clerks in the association decided to employ the methods of violence which were used by the employees of shops for novelties and the grocers' clerks. About three hundred collected before the drug-stores in question and created a disturbance. The threatened pharmacists have no intention of yielding while the drug clerks have declared their intention of renewing the agitation each night. The police is going to take measures to protect the pharmacists.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, July 27, 1910.

Personal

July 16 the senior of German pediatricians, and indeed of pediatricians in general, Prof. E. Henoch, celebrated his ninetyeth birthday. He has lived in Dresden since leaving the Berlin faculty and enjoys comparatively great physical and mental vigor. At his jubilee congratulations were sent to him from all sides, including those of the imperial couple, who regard themselves as indebted to him for the care of their children.

The University of Edinburgh has awarded Professor Bier the Cameron prize, which was offered by the university for that benefactor of mankind who should have made an especially important step in the progress of medicine during the last five years.

Professor Feer of Heidelberg has received a call to Zürich as pediatrician.—The search for a successor of Professor Bumm, who, as is well known, has received the chair of Professor Olshausen, is now happily finished. In order to avoid further declinations a gynecologist was chosen who it could be assumed would surely accept, namely, Professor Franz of Kiel. Professor Franz is a former assistant of Bumm, aged 36; he has accomplished little of importance and is scarcely known in the wider German medical circles, to say nothing of foreign countries. The same procedure has been followed here as in the case of the successor of von Leyden, when Professor His was selected because it was thought that no better investigator could be got. In this way, at any rate, the fame of the Berlin medical faculty is diminishing, since it has lost Virchow, Helmholtz, Dubois Reymond and Koch.—Professor Olshausen has been given a title of nobility on his departure from the faculty. Medical titles of nobility with us will soon be as common as blackberries.

Insurance Against Mental Disease

The attempt to transfer the burdens of the individual by means of insurance to the shoulders of the many has been extended by a German psychiatrist (Medical Councillor Fischer) to the provision for the care of the insane. The idea of insuring against insanity may seem strange at first sight; but insanity is not so rare and when it occurs it affects the life of the family quite as much as any other misfortune against which insurance is commonly secured. Fischer recommends insurance in connection with an institution for annuity and life insurance. In Nuremberg there has been for twenty-five years a society that makes a business of such insurance.

Admission to the Berlin Faculty

This question, which I have previously treated, has reached a new stage. The minister of education has informed the faculty that he contemplates repealing the secret ballot in the voting on the admission of new privat-docents. This method was introduced by the faculty in 1904 because its members believed that in this way their mutual independence would be better preserved, especially when the election of an assistant of an influential professor was under consideration. The faculty will undoubtedly agree with the view of the minister, inasmuch as this plan has had in fact no influence on the great excess of privat-docents admitted. As to the proposal to elect privat-docents for a short period, the minister has not yet expressed an opinion, but his decision may be unfavorable. For the removal of the nuisance complained of there remains as the surest method simply the principle to impose the strictest scientific requirements for admission. Evidence in favor of this is afforded by the fact that in the last semester not a single privat-docent has been admitted to the medical faculty.

Campaign Against Alcoholic Intemperance Among Children

To avoid the dangers that the use of alcohol entails on children the German Association Against the Misuse of Alcoholic Beverages prepared a warning circular which is to be distributed to parents under the direction of the Prussian department of education on occasion of public vaccination, medical inspection of schools, etc. The teachers are to speak of the circulars while teaching and place them in the school books, and they are also distributed by the midwives to lying-in women and by the officials at the announcements of births and weddings, and by factory managers, paymasters, ministers, etc. Altogether in this way 2,000,000 copies of this circular were distributed in 1909.

Marriages

HARRY D. CARTMELL, M.D., to Miss Oradelle DeMoulin, both of Greenville, Ill., August 11.

C. HUGH McKENNA, M.D., to Miss Evelina Marguerite Beauvais, both of Chicago, August 10.

HERBERT SEYMOUR GAY, M.D., to Miss Marjorie Florence Dearborne, both of Boston, August 3.

WARREN D. MILLER, M.D., Weaver, W. Va., to Miss Louise Davis Lawrence, at Baltimore, August 6.

THOMAS ROY CAMPBELL, M.D., Arthur, N. D., to Miss Margaret Adile Luse, of Iowa City, Iowa, August 11.

OSCAR R. MICKLETHWAIT, M.D., Portsmouth, Ohio, to Miss Laura Allen, of Jackson, Ohio, at St. Charles, Mo., recently.

Deaths

William Frederic Ridgway, M.D. Jefferson Medical College, Philadelphia, 1904; a member of the American Medical Association; pathologist to the Atlantic City, (N. J.) Hospital; died at that city, August 5, following an operation for appendicitis, aged 38. Resolutions were passed on his death by the Atlantic County Medical Society.

William Newlon Miller, M.D. Jefferson Medical College, Philadelphia, 1852; a member of the Medical Society of the State of Pennsylvania; a veteran of the Civil War; said to have been the oldest practicing physician in Allegheny County; died at his home in Pittsburg, August 3, from pneumonia, aged 83.

James Lot Bullock, M.D. Meharry Medical College, Nashville, Tenn., 1895; a member of the National Medical Association; secretary of the North Carolina State Medical, Dental and Pharmaceutical Association for several years; died at his home in Greensboro, February 14, from tuberculosis, aged 39.

Silas Smith Cartwright, M.D. College of Physicians and Surgeons, New York City, 1853; a veteran of the Civil War; a member of the legislature from Delaware County in 1884 and 1885; postmaster of Roxbury, N. Y.; died at his home in that place, July 31, from heart disease, aged 76.

Abraham S. Raudenbush, M.D. Jefferson Medical College, Philadelphia, 1864; a member of the American Medical Association; one of the founders of the Reading (Pa.) Hospital and for some years a member of its staff; died suddenly at Pottstown, Pa., August 5, aged 69.

Edwin C. Buell, M.D. New York Homeopathic Medical College and Hospital, 1876; a member of the California State Board of Medical Examiners from 1901 until 1907; of Los Angeles; died in Genoa, Italy, while touring Europe, July 20, from appendicitis, aged 57.

James P. Moore, M.D. Medical College of the State of South Carolina, Charleston, 1852; a member of the American Medical Association; surgeon in the Confederate Army during the Civil War; died at Yazoo, Miss., August 5, from cholera morbus, aged 83.

George B. Jennings, M.D. Medical College of Virginia, Richmond, 1860; a member of the Medical Society of Virginia; for twelve years superintendent of schools of Green County, Virginia; died at his home in Ruckersville, August 2, from heart disease, aged 72.

Francois H. DeVaux, M.D. Hospice Bicetre, Paris, 1867; for a number of years United States army surgeon; at one time superintendent of the State Board of Health of North Dakota; died at his home in Chicago, August 7, from angina pectoris, aged 59.

Chesterfield W. Harper, M.D. George Washington University, Department of Medicine, 1860; contract surgeon for the United States army during the Civil War; was found dead in his room at Russellville, Ky., August 5, from heart disease, aged 74.

Theodore M. Togus, M.D. University of Vermont, College of Medicine, Burlington, 1886; a member of the New Hampshire Medical Society; a member of the board of health of Hookset, N. H.; died at that place, July 28, from heart disease, aged 57.

Joseph R. Ryan, M.D. University of Louisville (Ky.) Medical Department, 1865; surgeon in the Union army during the Civil War; of Des Moines, Iowa; died at the home of his daughter in Waterloo, Iowa, August 2, from cancer, aged 70.

John J. A. Burke, M.D. University of Buffalo (N. Y.) Medical Department, 1877; for nine years health officer of Rochester, N. Y.; died at Clifton Springs, N. Y., where he had gone for treatment, August 1, from paralysis, aged 60.

Frank Camm, M.D. University of Maryland, School of Medicine, 1885; a member of the Medical Society of Virginia; assistant surgeon at Camp Alger during the Spanish-American war; died at Lynchburg, August 5, aged 62.

Jesse S. Reagan, M.D. Rush Medical College, Chicago, 1854; a member of the Indiana State Medical Association; a practitioner of medicine in Indiana for fifty-seven years; died at his home in Lebanon, February 9, aged 81.

Levi Drakely Rood, M.D. University of Vermont, College of Medicine, Burlington, 1881; a member of the American Medical Association; died at his home in Des Moines, Iowa, August 8, from appendicitis, aged 49.

Charles Edwin Shumard, M.D. Cincinnati College of Medicine and Surgery, 1891; a member of the Cincinnati Academy of Medicine; died at his home in Venice, Ohio, August 2, from angina pectoris, aged 48.

Nathaniel Seward Parsons, M.D. University of Vermont, College of Medicine, 1874; a member of the Illinois State Medical Society; died at his home in Kewanee, Ill., August 8, from Bright's disease, aged 56.

James Henry, M.D. Bellevue Hospital Medical College, New York City, 1870; a veteran of the Civil War; formerly of LaHarpe, Ill.; died at his home in Galesburg, Ill., August 2, from paralysis, aged 69.

Nathaniel C. Wilson, M.D. University of Pennsylvania, Department of Medicine, 1853; a retired practitioner of Houston Heights, Texas; died at his home in that city, August 5, aged 93.

John Adam Krug, M.D. Medico-Chirurgical College of Philadelphia, 1889; a member of the Medical Society of the State of Pennsylvania; died at his home in Philadelphia, August 6, aged 54.

William Gilman Perry, M.D. College of Physicians and Surgeons, New York City, 1847; a trustee of the state hospital for many years; died at his home in Exeter, N. H., August 2, aged 87.

Myron E. Knapp, M.D. Chicago Homeopathic Medical College, 1882; of Detroit, Mich.; died at the home of his sister in Byron, Mich., July 29, from cerebral hemorrhage, aged 62.

Charles S. Parker, M.D. Castleton (Vt.) Medical College, 1847; a practitioner at Three Mile Bay, N. Y., for more than sixty years; died at his home in that place, July 28, aged 89.

Gustave Aftel, M.D. University of Warsaw, Russia, 1869; a member of the Ohio State Medical Association; died at his home in Toledo, August 5, from septic poisoning, aged 60.

John H. Whitehead, M.D. Homeopathic Hospital College, Cleveland, Ohio, 1874; a veteran of the Civil War; died at Bowling Green, Ohio, August 6, from diabetes, aged 69.

Solomon Secord, M.D. Medical Department of Victoria College, Toronto, Ont., 1856; a Confederate veteran; died suddenly at his home in Kincardine, Ont., April 24, aged 76.

Charles H. Moore, M.D. University of Pennsylvania, Department of Medicine, 1868; a veteran of the Civil War; died at his home in Wheeling, W. Va., July 28, aged 67.

Joseph H. Lukens, M.D. Eclectic Medical College of the City of New York, 1875; a retired practitioner of Seattle, Wash.; died at his home in that city, July 23, aged 67.

George William Harrison, M.D. Miami Medical College, Cincinnati, 1873; formerly of Newtonia, Mo.; died at Chester, Mo., August 2, from heart disease, aged 58.

Frederick Augustus Jewett, M.D. Harvard Medical School, Boston, 1852; a member of the Massachusetts Medical Society; died in Grafton, February 8, aged 85.

William Leslie Dewees, M.D. Medical College of Indiana, Indianapolis, 1883; died at Mooresville, Ind., August 5, from cerebral hemorrhage, aged 60.

Edwin Cowles, M.D. Hahnemann Medical College, Chicago, 1866; died at his home in El Dorado, Kan., July 28, from paralysis agitans, aged 80.

John Jackson Brower, M.D. Eclectic Medical Institute, Cincinnati, 1869; died at his home in Coshocton, Ohio, July 30, from paralysis, aged 71.

Lycurgus Coon, M.D. Physio-Medical Institute, Cincinnati, 1868; died at his home in Springfield, Mo., August 6, from tuberculosis, aged 72.

Pharmacology

[CONTRIBUTION FROM THE CHEMICAL LABORATORY OF THE AMERICAN MEDICAL ASSOCIATION]

AROMATIC DIGESTIVE TABLETS

W. A. Puckner and L. E. Warren

It has been amply demonstrated¹ that pepsin and pancreatin, when in solution, mutually destroy each other; if the solution be acid, the pepsin destroys the pancreatin; if alkaline, the pancreatin destroys the pepsin. By using the characteristic effect of pepsin on proteids in acid medium and that of pancreatin on proteids and starches in an alkaline solution it can readily be demonstrated that commercial liquid preparations labeled as containing both of these ferments actually contain only one ferment. They are misbranded.

Besides the liquid a goodly number of solid preparations, chiefly tablets, containing pepsin and pancreatin are offered to the profession. Among these are tablets consisting simply of pepsin and pancreatin. Since pepsin and pancreatin interact only when in solution, it is quite possible to prepare tablets which contain these ferments. The use of these tablets is unscientific, since one or the other of the ferments is destroyed when it comes in contact with the fluids of the digestive tract. In addition to simple tablets containing pepsin and pancreatin only there is at present a host of "digestive tablets" on the market. Among these are some which must be classed with the "digestive impossibilities" (Reports of the Council on Pharmacy and Chemistry, 1910, vol. 1, p. 41). The preparations referred to are tablets claimed to contain pepsin, pancreatin, diastase, hydrochloric acid and lactic acid. When it is considered that the United States Pharmacopeia defines hydrochloric acid as "a liquid composed of 31.9 per cent. by weight of absolute hydrochloric acid ($HCl=36.16$) and 68.1 per cent. of water," i. e., a solution of hydrogen chlorid, a gas, in water, it would at first appear that the incorporation of any appreciable quantity of hydrochloric acid in tablets would be impracticable. Hydrochloric acid, however, possesses to a limited extent the property of combining loosely with protein substances so that it becomes possible to bring about its combination with pepsin and similar substances to form compounds which are relatively stable at ordinary temperatures. Because of the volatility of the free acid and its limited combining power with protein substances (100 gm. boiled beef combined with 2 gm. absolute hydrochloric acid²), the quantity of acid in any tablet can never be large, much less than sufficient to be of any therapeutic value.

A number of firms offer "digestive tablets" for sale having formulas of which the following may be considered typical:

Sacch. Pepsin.....	4	grains
Pure Pancreatin.....	1	grain
Diastase	¼	grain
Aromatic Powder.....	¼	grain
Lactic Acid.....	¼	grain
Hydrochloric acid.....	¼	grain

Some manufacturers use United States Pharmacopeia pepsin in place of the saccharated article; others do not give the exact quantities of hydrochloric acid which their product is supposed to contain, but make use of the indefinite expression "q. s.," still others state merely that hydrochloric acid is present, but make no claim whatever concerning the quantity.

From purely theoretical considerations it is possible that the tablets referred to might contain appreciable amounts of hydrochloric acid. Since the formulas for some of the tablets furnish no information concerning the content of hydrochloric acid, it seemed worth while to determine the quantity, if any, actually present in some of the tablets on the market. Accordingly a trade package of "digestive aromatic tablets," as put up under the label of each of six American manufacturers, was purchased and submitted to examination in the Association laboratory.

Qualitative tests made on specimens from each brand of tablets demonstrated the absence of uncombined hydrochloric

acid in each. Further tests³ showed that hydrochloric acid in protein combination was present essentially in the amounts claimed in three of the specimens. In two of the others hydrochloric acid was entirely absent; in the remaining one only the merest traces of hydrochloric acid could be found.

H. K. MULFORD COMPANY

"DIGESTIVE AROMATIC"

"Pepsin, Sacch.	4	grains
"Pancreatin	1/2	grain
"Diastase	1/16	grain
"Acid Lactic.....	1/8	grain
"Acid Hydrochloric.....	1/8	grain
"Aromatic Powder.....	1/4	grain

Dose: 1 or 2 tablets.

In the above formula each tablet is said to contain ½ grain hydrochloric acid. This amount is equivalent to 0.002584 gm (1/25 grain) absolute hydrochloric acid. Analysis demonstrated that each tablet contains about 0.00267 gm. hydrochloric acid (absolute HCl) or essentially the amount claimed. The average dose of diluted hydrochloric acid United States Pharmacopeia is 1 c.c., equivalent to 0.1049 gm. absolute hydrochloric acid. To obtain this quantity from the above preparation the patient would be required to swallow more than three dozen of the tablets.

WM. S. MERRELL CHEMICAL COMPANY

"DIGESTIVE AROMATIC, 5 GRAINS"

"Pepsin	80	parts
"Pancreatin	10	parts
"Diastase	1	part
"Acid Lactic.....	1	part
"Acid Hydrochloric.....	3	parts
"Aromatic Powder.....	5	parts

Calculation shows that each tablet should contain about 0.0031 gm. of absolute hydrochloric acid. The analysis indicated that each tablet contains about 0.0030 gm. hydrochloric acid (absolute HCl) in protein combination, or practically the amount claimed. One pharmacopeial dose of hydrochloric acid is contained in 35 of the tablets.

PARKE, DAVIS & COMPANY

"DIGESTIVE AROMATIC"

"Saccharated Pepsin.....	4	grains
"Pure Pancreatin.....	1	grain
"Diastase	¼	grain
"Aromatic Powder.....	¼	grain
"Lactic Acid.....		
"Hydrochloric Acid.....		

Dose: 1 to 3 tablets.

Chlorid is present in small amounts, but quantitative examination indicated that hydrochloric acid, either free or in protein combination, is absent. An ammonium salt is present in small quantities.

SHARPE & DOHME

"DIGESTIVE AROMATIC"

"Pepsin, Sacch., U. S. P.....	4	grains
"Pancreatin, pure.....	1	grain
"Diastase	¼	grain
"Aromatic Powder.....	¼	grain
"Lactic Acid.....	q. s.	
"Hydrochloric Acid.....	q. s.	

Small quantities of chlorid are present. Quantitative examination indicated that hydrochloric acid in protein combination is present only in very small amounts, each tablet containing but about 0.00034 gm. of absolute acid, or about 0.34 per cent. of the pharmacopeial dose. Ammonia is absent. Inasmuch as more than 300 of these tablets would be required to furnish a pharmacopeial dose of hydrochloric acid, this firm's interpretation of the expression "q. s." would prove interesting.

TRUAN, GREENE & COMPANY

"SYNERGIA"

"Synergia" is claimed to be composed of "pepsin, pancreatin, veg. diastase, lactic acid, hydrochloric acid and aromatics; dose, 1 to 3 tablets." The specimen contains no hydrochloric acid, either free or protein combination. A trace of ammonia and small quantities of chlorid were found.

1. U. S. Pharmacopeia, 8th revision, p. 334; THE JOURNAL A. M. A., Feb. 2, 1907, and Feb. 9, 1907.
2. Hemmeter, Diseases of the Stomach, Edition 3, p. 250.

3. The details of the analysis will be sent on receipt of a stamped envelope; they will also be published in the annual report of the Chemical Laboratory.

THE FRASER TABLET COMPANY

"Pepsin Sacch.	80 parts
"Pancreatin, Pure.	10 parts
"Diastase	1 part
"Lactic Acid.	1 part
"Hydrochloric Acid.	3 parts
"Aromatic Powder.	6 parts

Dose: 1 or 2 tablets.

"Each tablet represents (5) grains of the above mixture."

According to the formula hydrochloric acid (31.9 per cent. absolute HCl) represents 3 parts in 101 of the preparation from which the tablets are made. Each tablet (containing 5 grains of the mixture) should have 0.00307 gm. absolute hydrochloric acid. Analysis showed that each tablet contains hydrochloric acid in protein combination equivalent to an average of 0.003066 gm. absolute hydrochloric acid, or essentially the amount claimed. It would be necessary to give 34 tablets to administer a pharmacopeial dose of hydrochloric acid.

EDITORIAL NOTE: The above indicate that the use of such tablets is irrational, unscientific and should be condemned. The only constituent of these tablets, other than the aromatics, which might possibly be of benefit in stomach troubles, is the pepsin. But even if it be assumed that the diastase and pancreatin could exert their characteristic effects, their aid to digestion (metabolism) would be but slight, because their amounts in the tablets are too small to be of any value.

It is claimed that the tablets contain diastase in amounts varying from 1/20 to 1/4 grain. Assuming the diastase used to be of first-class quality, i. e., capable of converting 200 times its own weight of starch into soluble products, the quantity in one tablet would be capable at the most of digesting but from 10 to 50 grains of starch, an amount equal at the most to but a small spoonful of oatmeal or a very dainty bite of bread. In the same way the quantity of pancreatin is insufficient to be of any material aid in digestion should it in some way escape destruction in the stomach and still retain its full activity when it reaches the alkaline juices of the intestines. One grain of pancreatin of full United States Pharmacopeia strength will digest only 25 grains of starch or the proteids in about 100 c.c. of milk.

Saccharated pepsin, which was formerly official, was required to digest 300 times its own weight of moist egg albumin, while the pepsin that is now official is required to digest ten times that amount, or 3,000 times its own weight. It is evident, therefore, that the tablets should contain sufficient pepsin to digest appreciable amounts of protein. No intelligent physician would prescribe these tablets simply for the pepsin they contain or are supposed to contain; if he wanted to give pepsin he would prescribe the drug in the simple form.

Clinical experience has shown that in the majority of cases of so-called dyspepsia the stomach contents contain too much rather than too little hydrochloric acid, and wherever there is a sufficiency of acid there is usually no decrease in the secretion of pepsin. In many, of such cases, too, digestion is normal, or even more active than normal, but even when it is imperfect there is seldom any lack of pepsin.

Insufficient digestive power is most often due to a deficiency of hydrochloric acid and not to lack of pepsin in the stomach contents. In the tablets under consideration, however, hydrochloric acid is present—if at all—in the most ridiculously minute quantities; quantities that are so small as to preclude any therapeutic effect except that due to the psychic element.

These tablets, with their six or more ingredients, are typical "shotgun prescriptions." Such prescriptions catch the unthinking doctor as well as the self-drugging public, for, while clinical experience and physiologic experiments have demonstrated that the old ideas regarding the value of these digestives and ferments were erroneous, the public and many members of the medical profession still seem to be influenced by the old theories.

In conclusion we must not lay all the blame on the manufacturing firms for supplying these absurd combinations; the physician who prescribes them should assume a large share of it. If the doctors did not use them the manufacturing concerns would soon stop putting them on the market. We hope, however, that those manufacturing concerns that like to be classed as reputable will cease to disgrace their catalogues with what they know to be therapeutic absurdities.

Lung Germine

To the Editor: I was much interested in the article on "Lung Germine" that appeared in *THE JOURNAL*, Aug. 6, 1910. Two years ago, when I was at Adell, Wis., a young man, aged 26, came to my office complaining of "lung trouble." His temperature was 103 F., pulse 120, appetite poor and he had lost weight in about eight weeks from 170 to 130 pounds. He complained of great weakness, shortness of breath, persistent cough and sleeplessness. I found a tuberculous patch in the right upper lobe and the examination of the sputum was positive. I put him on the open air treatment, rest, diet, etc. Six months later his temperature was normal; his weight had increased from 130 to 165 pounds, expectoration and cough very much decreased; he slept well, had a ravenous appetite and was able to take long walks without tiring himself.

About this time he called on me and wanted to know when he could go to his work again as bookkeeper. I advised him to wait another six months. This apparently seemed too long for him and he got in correspondence with the Lung Germine Co., and began to take their Lung Germine. Immediately after he commenced using it, he became weaker, began to show signs of cyanosis in the tips of his fingers and ears; was very restless, lost appetite and could not sleep. From day to day he grew worse, but on communicating with "Dr." C. R. Wendt of the Lung Germine Company, he was told to keep right on with the medicine as these were favorable symptoms and he surely would get well. In 10 or 12 days I was called in to see him. I found him very cyanosed over the entire body with frothy expectoration from the mouth and nose and very rapid breathing. Five minutes later he was dead. I called a coroner's inquest and signed the death certificate; cause of death due to the use of Lung Germine.

After the patient's death, I wrote to the Michigan State Board of Medical Examiners and asked for information concerning this Dr. C. R. Wendt. The secretary informed me that Dr. C. R. Wendt had no license to practice medicine in Michigan.

C. U. SENN, M.D., Milwaukee, Wis.

COMMENT: The experience of our correspondent seems to verify the statement made in the exposé of this wretched fraud, viz., that the nostrum is not only worthless but positively dangerous. If it were possible to get information on the point, we do not doubt that it would be found that hundreds of poor victims had had their lives very materially shortened by the use of this vile concoction.

"Every man who trades in this market, whether he pockets the profits of the maker, the purveyor or the advertiser, takes toll in blood. He may not deceive himself here, for here the 'patent medicine' business is nakedest, most cold-hearted. Relentless greed sets the trap and death is partner in the enterprise."

Correspondence

One Medical Aspect of the Prize Fight

To the Editor: The medical man may read much between the lines as to the reason for the defeat of a former champion in a recent famous prize-fight. There was much more at the bottom of this inglorious disaster than mere inability to get back into training.

The stress laid on the reports, at the time of the early arrangements for the fight, that the former champion had been examined by noted medical men to see if he could expect to get into good training again, together with the current rumors as to the habits of dissipation common to this class of athletes, would give ground for the suspicion that there may have been a definite and specific reason for such a careful preliminary examination. One noted ring follower states that no man with a normal brain could have been so utterly helpless before an opponent; another that "he was as helpless as an old woman;" another writer states that the victor delivered fifty-five blows while the loser gave but fourteen, and that not one of these did any particular damage. One of the seconds states in an interview that the loser

swayed so in walking down the aisle to the ring that he (the second) twice supported the champion by laying a hand on each shoulder to keep him from falling. The picture published by a prominent national weekly shows the fighter with his feet spread so far apart that the two legs defined an equilateral triangle. The prize-fighter complained afterward that he saw double during the fight; that he could not estimate the distance of his opponent; that he saw plenty of openings for good blows but could not get his fist there in time. The papers were filled with reports of the attempts of reporters and visitors to see the champion in his boxing practice, but he would not box before prying eyes, even practicing at 3 a. m. to avoid observation.

Such evidences of mental failure, ataxia and incoordination point almost certainly toward some degenerative process affecting the nervous system, the cause of which it is not difficult to imagine.

J. N. HALL, M.D., Denver.

Fixing the Eyeball in Cataract Extraction

To the Editor: Since the publication of my paper, read at the St. Louis meeting, I have been informed by my friend, Dr. Ziegler of Philadelphia, that my method of fixing the eyeball in cataract extraction was first resorted to by Macnamara. The following is quoted from page 54 of the fourth edition of his book: "Suppose the right eye is to be operated on; the surgeon, standing behind his patient, with a pair of fixing forceps, seizes a fold of the conjunctiva, together with the tendon of the internal rectus, so as to have a steady, firm hold on the eyeball." On page 56 he mentions the fact that the tendon grasp is continued while he dislocates and delivers the cataract with a scoop. Of course I must surrender my claim of originality, so far as the grasp of the tendon of the internal rectus muscle is concerned. My astonishment is that this method, although introduced prior to 1882, disappeared from both practice and literature, and I knew nothing about it until it occurred to me to put it into practice. There is no other method of fixation comparable to it. My other claims, as made in my paper, have not been refuted, and I am sure cannot be. Please publish this as a full surrender of my claim on fixation of the globe by a grasp of a tendon of the internal rectus.

G. C. SAVAGE, Nashville, Tenn.

The Dependence of Neurology on Internal Medicine *

To the Editor: I think the article by Drs. Joseph Collins and Pearce Bailey, of New York (THE JOURNAL, July 30, 1910, p. 393), was read with great interest and received extensive comment by those of us who are interested in the teaching of neurology. As a general proposition most of the premises advanced by the authors of this article are correct. All of us are agreed that neurology has been neglected, both in the lecture room and hospital ward, but the statement that "In all America there is scarcely a general hospital with neurologic wards worthy of the name, etc.," will not hold water. So with the statement "The profession who teaches them having no hospital patients of their own can demonstrate only such patients as are able to walk to the clinic;" and so on throughout the entire article are many statements that are really misleading and do an injustice to some of our neurologists and general hospitals.

Last year I did neurologic work at the University of Pennsylvania. I found the neurologic wards in Blockley Hospital properly organized and containing over four hundred patients; among this number could be found all of the ordinary nervous diseases and many of the unusual and rare ones. These wards were organized in 1877 by Dr. Charles K. Mills, and all of the material found in them is available for teaching purposes by the medical colleges of Philadelphia; and for many years ward classes have been a prominent feature in neurologic teaching in this hospital.

* Another letter on this subject is published in THE JOURNAL Aug. 13, 1910, page 613.

The attending neurologic staff at Blockley has an equal standing with the attending physicians and surgeons. Cases are assigned directly to them; they are studied by separate interns and the department of neurology is just as much an independent unit of the organization controlling the hospital, as is the surgical or medical. Post-mortems are conducted under the direction of the attending neurologist, and the material is properly worked up and studied by his assistants and the hospital pathologist.

Neuropathology is comparatively new in America; but this branch is now receiving careful attention in all of our medical schools. I have no doubt that within a few years the courses in this branch offered to students in America will compare very favorably with those given in the laboratories abroad; in fact I have been told by men who have taken extensive work in Europe that the work of American investigators and teachers of neurology is attracting attention and receiving the favorable consideration to which it is entitled.

So while we cannot point to any endowed institutions for the special study of nervous diseases, let us be thankful that most of our new municipal hospital boards are recognizing the importance of giving this branch more attention, and buildings are being constructed with the idea of providing for the better care and proper study of nervous cases, and that competent neurologists are being appointed on the staffs holding equal rank with the surgeon and internist.

R. E. CASTELAW, Kansas City, Mo.

Registration of Foreign Physicians

To the Editor: Dr. Hoenes in his letter on this subject (THE JOURNAL, Aug. 6, 1910, p. 520) certainly makes an exceedingly important, though neglected, point. During the development of North Dakota, Canadian physicians rushed in, and now very largely occupy the land. What is true of North Dakota is probably true of other northern states. But when one of us wants to get into some virgin territory in Canada, he is blocked at the very start. This matter should be taken up by our legislatures. I hope that you will use your influence and call attention to it often.

C. E. McREYNOLDS, M.D., Goodrich, N. D.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

WHAT IS THE DISEASE?

To the Editor:—A peculiar disease has been observed in a family. It resembles hoof and foot disease in animals. The attack is sudden; the disease starts between the toes and spreads to the heel. Itching, large vesicles which run together, high fever, delirium, and a very bad odor, like decayed animal matter, are features. The pain after four days extends up to the leg. The disease seems to be highly infectious. What can it be?

F. P. DORSEY, Hartington, Neb.

CAPITALIZATION IN PRESCRIPTIONS

To the Editor: In writing the following in prescriptions should the I and P be capital letters?

R. Fluidextracti cannabis indicæ
Balsami peruviani

P. W. BUSHONG, Pittsburg, Pa.

ANSWER: In writing the Latin of prescriptions there is a tendency to follow national usage. Thus in foreign pharmacopœias and prescriptions, nouns are frequently capitalized as in the native language, while the adjectives, even when derived from proper names, begin with a lower-case letter. On the other hand, the custom in Latin texts is to capitalize the adjectives derived from proper names, i.e., *populus Romanus*. This would seem to afford authority for beginning the words referred to in the query with capitals. Most books on medical Latin capitalize the second term of a pharmaceutical title in prescriptions as a rule, so that they afford no guide in the particular case under discussion. The usage of works on pharmacology is divided but the majority print these words with lower-case letters. There is a tendency in English for the proper adjective to change its capital initial to lower-case after long usage, and this may account for the similar tendency in the Latin of prescriptions. We may conclude therefore that the preponderance of the best usage is in favor of using lower-case letters.

ELECTRIC ANESTHESIA

To the Editor:—Please give references to be found in medical literature, if any, giving facts concerning the use of electricity as an agent for producing anesthesia. D. M.

- ANSWER.—Robinovitch, L. G.: *Electric Anesthesia*, Jour. Ment. Path., viii, No. 3, 1908.
Leduc, S.: *Electric Sleep*, Presse Médicale, 1907, xv, 129. Abst. in THE JOURNAL, April 6, 1907, p. 1220.
Tait, D., and Russ, R.: *Electric Sleep*, THE JOURNAL, Nov. 13, 1909, p. 1611.
Johnson, M. M.: *Electric Anesthesia*, Med. Rec., April 23, 1910; abstr. in THE JOURNAL, May 7, 1910, p. 1577.

ACUTE INDIGESTION AND SUDDEN DEATH

To the Editor:—Please give me references to some of the latest literature on so-called acute indigestion as the cause of sudden death. W. H. J.

ANSWER.—We find no references to this subject in recent literature. Brouardel ("Death and Sudden Death," Edition 2, 1902) refers to cases in which sudden death was supposed to be due to acute indigestion, but concludes that the evidence that indigestion was the sole or principal cause is insufficient. He says (p. 274), "I have read all the cases which authors have recorded, but I have not met with a single case in which preexisting lesions in other organs than the stomach were not sufficient to account for death; in most cases the patient had some renal affection, or was convalescent from typhoid fever."

X-RAY STERILITY

To the Editor:—Is the sterility produced by the x-ray permanent, or only temporary; and how long exposure will produce the same? Does it affect male and female alike? B. Y.

ANSWER.—The duration of sterility produced by the x-ray depends on the length of exposure, the distance of the tube, etc. The effect will be permanent if the exposures are of sufficient duration. The organs of the female are better protected from the rays than are those of the male, but, aside from this, both sexes are affected.

The Public Service

U. S. Public Health and Marine-Hospital Service

Changes for the 7 days ended Aug. 10, 1910:

- Guiteras, C. M., surgeon, granted 4 days leave of absence from Aug. 9, 1910.
Stimpson, W. G., surgeon, granted 20 days leave of absence from Aug. 11, 1910.
Blue, Rupert, surgeon, granted 8 days leave of absence from Aug. 7, 1910.
Moore, Dunlop, passed asst.-surgeon, granted 14 days leave of absence from Aug. 10, 1910.
Fox, Carroll, passed asst.-surgeon, relieved from duty in the Hygienic Laboratory and directed to proceed to Manila, P. I., and report to the Chief Quarantine Officer for duty, Aug. 5, 1910.
Vogel, C. W., passed asst.-surgeon, granted 15 days leave of absence from Aug. 10, 1910.
Glover, N. W., passed asst.-surgeon, leave of absence for 10 days from July 25, 1910, amended to read 3 days from July 25, 1910.
Bahrenburg, L. P. H., passed asst.-surgeon, granted 6 days leave of absence from July 26, 1910, on account of sickness.
Cleaves, F. H., acting asst.-surgeon, granted 6 days leave of absence from Aug. 1, 1910.
Deerhake, Wm. A., acting asst.-surgeon, granted 5 days leave of absence in July, 1910, under paragraph 210, Service Regulations.
Elfers, J. G., acting asst.-surgeon, granted 30 days leave of absence from Aug. 8, 1910.
Hart, George C., acting asst.-surgeon, granted 12 days' leave of absence from Aug. 18, 1910.
Hornings, Henry, acting asst.-surgeon, granted 7 days' leave of absence from Aug. 3, 1910, under paragraph 210, Service Regulations.
McLarty, A. A., acting asst.-surgeon, granted 10 days' leave of absence from Aug. 1, 1910.
Onuf, B., acting asst.-surgeon, granted 8 days' leave of absence from Aug. 16, 1910.
Richter, H. C., acting asst.-surgeon, granted 30 days leave of absence from Aug. 1, 1910.
Rush, John O., acting asst.-surgeon, granted 14 days' leave of absence from Aug. 10, 1910, with pay, and 4 weeks' leave of absence from Aug. 24, 1910, without pay.
Savage, Walter L., acting asst.-surgeon, granted 30 days' leave of absence from Aug. 12, 1910.
Schwartz, Louis, acting asst.-surgeon, granted 7 days' leave of absence from Aug. 8, 1910, under paragraph 210, Service Regulations.
Stevenson, J. W., acting asst.-surgeon, leave of absence for 30 days from Aug. 3, 1910, amended to read 30 days from Aug. 8, 1910.

Stewart, W. J. S., acting asst.-surgeon, granted 1 month's leave of absence without pay from July 23, 1910.

Townsend, W., acting asst.-surgeon, granted 8 days' leave of absence from July 28, 1910.

Wallace, C. R., acting asst.-surgeon, granted 14 days leave of absence from Aug. 22, 1910.

Medical Department, U. S. Army

Changes for the week ended Aug. 13, 1910.

Boyer, Perry L., capt., relieved from temporary duty at Fort Mason, Cal., and as attending surgeon, San Francisco, and on expiration of present sick leave of absence will proceed to Fort Clark, Tex., for duty.

Collins, C. C., major, on expiration of present leave of absence will proceed to Fort Robinson, Neb., for duty.

Church, James R., major, relieved from duty at Fort Robinson, Neb., and ordered to Fort Ontario, N. Y., for duty.

Gray, William W., col., ordered to proceed to Omaha, Neb., and report Sept. 1, 1910, for temporary duty as Chief Surgeon, Department of the Missouri.

Brechemin, Louis, col., relieved from duty in the Philippines Division, and will proceed on the transport to sail from Manila, P. I., Jan. 15, 1911, to San Francisco. Colonel Brechemin will proceed thence to Omaha, Neb., for duty as Chief Surgeon, Department of the Missouri, relieving Colonel William W. Gray, Medical Corps, who will return to his proper station.

Brownlee, Charles Y., major, on expiration of leave of absence will proceed to Fort Des Moines, Iowa, for duty at that post.

Vose, William E., major, relieved from duty at Fort Des Moines, Iowa, and ordered to Jackson Barracks, La., for duty at that post.

Usher, F. M. C., major, relieved from duty at Jackson Barracks, Mo., and ordered to Fort Sam Houston, Tex., for duty at that post.

Metcalfe, R. F., capt., on expiration of leave of absence will proceed to the Army General Hospital, San Francisco, Cal., for duty.

Vedder, Edward B., capt., detailed as a member of board for the purpose of studying tropical diseases as they exist in the Philippine Islands, vice Captain E. D. Kilbourne, Medical Corps, to take effect on departure of Captain Kilbourne from the Philippine Islands.

Casaday, George H., dental surgeon, relieved from duty at Presidio of Monterey, Cal., and will proceed from San Francisco, Sept. 5, 1910, to the Philippine Islands, for duty.

Graham, George D., dental surgeon, relieved from duty at Fort Leavenworth, Kan., and will proceed from San Francisco, Cal., Sept. 5, 1910, to Fort Shafter, H. Ty., for duty. Dental Surgeon Graham will stand relieved from Fort Shafter about December 15, and will then proceed to the Philippine Islands for duty.

Baker, Frank C., major; O'Connor, R. P., major, and Davis, William R., capt., August 4, will proceed at the proper time to the Camp of Instruction at Ft. Benj. Harrison, Ind., for duty, and on the completion thereof will return to their proper stations.

Smart, William, capt., August 4, granted 2 months' leave of absence about Sept. 7, 1910.

de Krafft, S. Chase, M.R.C., August 4, relieved from duty (active) in that Corps, to take effect Aug. 14, 1910.

Springwater, Samuel A., M.R.C., August 4, granted leave of absence to and including Sept. 4, 1910. First Lieutenant Springwater is honorably discharged from the service of the United States, to take effect Sept. 4, 1910, his services being no longer required.

Kremers, E. D., lieut., August 2, ordered to proceed from Presidio of San Francisco to Ft. Miley, Cal., for temporary duty.

Casper, Lieut. (Joseph), August 1, left Ft. Du Pont, Del., en route to Pine Camp, N. Y., for duty.

Lynch, Edward C., M.R.C.; Ferenbaugh, Thomas L., lieut.; Hughes, Leonard S., M.R.C., August 4, report for duty at Camp E. S. Otis, Wyoming.

Craig, Charles F., capt., August 5, directed to proceed to New York City and to New Haven, Conn., on official business pertaining to the Medical Department.

Hess, Louis T., Waterhouse, S. H., Geddings, Edward F., majors, August 4, assigned to duty as Inspector-Instructors at state encampment at Gettysburg, Pa., from Aug. 11 to 20, 1910.

Gibson, Paul W., M.R.C., July 30, left Ft. Yellowstone, Wyo., on practice march with Troop F, Fifth Cavalry.

Bundesen, H. N., M.R.C., August 4, left Ft. D. A. Russell, Wyo., en route to Camp E. S. Otis, Wyo.

Connor, C. H., major; Owen, Leartus J., capt.; Beery, Harry R., lieut., July 28, designated for duty at the Camp of Instruction, Fort Benjamin Harrison, Ind.

Vose, William E., major, Aug. 5, 1910, orders to duty; Camp of Instruction, Ft. Riley, Kan., revoked.

Smith, Allen M., major, August 1, in addition to his other duties, will assume charge of the office of the Chief Surgeon, Department of Texas.

Harris, H. J., M.R.C., August 9, reported for temporary duty at Pine Camp, N. Y.

Fauntleroy, P. C., major, August 4, detailed for duty as Inspector-Instructor, organized Militia of Illinois, encampment at Peoria, Ill., Aug. 20-27, 1910.

Hall, James F., capt., Aug. 5, 1910, ordered to make the physical examinations of captains and lieutenants on duty at Rock Island Arsenal, Ill.

Graham, George D., D.S., August 8, granted 10 days' leave of absence, Aug. 20, 1910.

Ingalls, R. E., dental surgeon, August 2, on completion of duty at Ft. Wingate, N. M., will proceed to Ft. Apache and Huchuca, Ariz., thence to Whipple Barracks, Ariz., for duty.

Hallett, H. J., M.R.C., August 9, reported at Fort Hamilton, N. Y., for temporary duty.

Register, E. C., M.R.C., August 11, reported for temporary duty at Ft. Michie, N. Y.

Maguire, David F., M.R.C., August 10, left Ft. Myer, Va., en route to Ft. McHenry, Md., for temporary duty, and reported at Ft. McHenry, Md., Aug. 11, 1910.

Robbins, Chandler P., major, August 8, left Ft. McHenry, Md., en route to Ft. Monroe, Va., for temporary duty.

Clayton, J. B., major, August 10, granted leave of absence for one month and fifteen days, about Oct. 1, 1910.

State Boards of Registration

North Dakota July Report

Dr. H. M. Wheeler, secretary of the North Dakota State Board of Medical Examiners, reports the written examination held at Grand Forks, July 5-7, 1910. The number of subjects examined in was 14; percentage required to pass, 75. The total number of candidates examined was 16, of whom 13 passed and 3 failed. Eleven candidates were licensed through reciprocity. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
Northwestern Univ. Med. School (1903)	80	(1910)	82, 86, 91
College of Physicians and Surgeons, Chicago	(1910)		89
Harvard Medical School	(1903)		88
Univ. of Mich., Dept. of Med. and Surg.	(1903)		90
Hamline University	(1909)		76, 83, 85
Jefferson Medical College	(1910)		82
Marquette University, Milwaukee	(1910)		78
University of Toronto, Ontario	(1908)		82

College	FAILED	Year
Chicago Physiomedical College	(1906)	*
Indiana University	(1909)	*
Queen's University, Kingston, Ontario	(1905)	*

College	LICENSED THROUGH RECIPROCITY	Year Grad.	Reciprocity with
Illinois Medical College	(1907)		Wisconsin
College of Phys. and Surg., Chicago (1905)	(1908)		Illinois
Northwestern University Medical School	(1908)		Illinois
Jenner Medical College	(1906)		Illinois
Detroit College of Medicine	(1896)		Wisconsin
University of Minnesota, College of Medicine, (1903)	(1905)		Minnesota
University of Michigan, Dept. of Med. and Surg.	(1907)		Michigan
Barnes Medical College	(1906)		Illinois
McGill University, Canada	(1906)		Minnesota

The following questions were asked:

ANATOMY

1. Describe the hip joint, naming ligaments.
2. Give a description of the femoral artery and its relations.
3. Describe circulation of blood through the heart.
4. Describe the scapula.
5. Describe the axilla and what does it contain?

PHYSIOLOGY

1. Give the physiology of the kidneys.
2. Describe the process of digestion of fats.
3. What is the function of bile?
4. How is the waste material of the body thrown off?
5. Describe the function of the eye.

HISTOLOGY

1. Describe karyokinesis.
2. Describe the different cells found in the blood.
3. Describe a cross-section of the stomach at pyloric end.
4. Describe a cross-section of the middle of a long bone.
5. Give the histology of the kidney.

PATHOLOGY

- Answer any five questions: 1. Describe atrophy and degeneration as separate pathologic conditions. 2. Describe a thrombus, embolus, an infarct. 3. Differentiate between a lipoma and malignant tumor. 4. Define inflammation. 5. Describe the pathologic changes in lung tissue resulting from tubercular infection. 6. Differentiate between sapremia and septicemia. 7. What are the postmortem appearances in typhoid fever? 8. Give the pathology of leukemia. 9. What pathologic conditions produce necrosis? 10. Describe the process of fatty degeneration.

OBSTETRICS

1. Describe the pelvic straits.
2. Give indications and technic of a high delivery.
3. Diagnose and treat a case of placenta previa.
4. What is your idea regarding causes of puerperal sepsis?
5. What would lead you to suspect some retained placenta in an old case (two weeks after delivery)? Give your treatment.

EYE AND EAR

1. Give prophylaxis and treatment of ophthalmia neonatorum.
2. Give prognosis and treatment of a cornea in which is imbedded a hot cinder.
3. Define (a) astigmatism, (b) blepharitis.
4. Define and give etiology of glaucoma.
5. Symptoms and treatment of chronic nonsuppurative median otitis.
6. Give indications for mastoid operation.
7. Give anatomic divisions of the ear and contents of each.
8. What is the best method of removal of a foreign body—as a pea—from the ear?

CHEMISTRY AND TOXICOLOGY

1. Define the followings terms as applied to chemistry: Reagent, reaction, insolubility, volatility, valency, atomicity.
2. Describe a method of detecting free HCl in stomach contents.
3. Describe a quantitative test for urea.
4. Give the Esbach method for quantitative test for albumen in urine.
5. Give the composition and physical properties of good drinking water.
6. Symptoms and treatment of poisoning by carbolic acid, corrosive mercury, opium, strychnin and arsenic.

PRACTICE

- Answer any five questions: 1. Give etiology, symptoms and treatment of auto-intoxication. 2. Give diagnosis of cerebral hemorrhage. 3. Differentiate between typhoid fever and malaria. 4. What are the symptoms of intestinal perforation in typhoid fever? 5. Give symptoms and treatment of measles. 6. Definition, symptoms and treatment of chlorosis. 7. Differential diagnosis between mitral stenosis and regurgitation. 8. Write a prescription and give diet list for chronic constipation. 9. Etiology and treatment of hay fever. 10. Differentiate between gastritis, carcinoma and ulcer of stomach.

PREVENTIVE MEDICINE

1. By what method can we prevent the occurrence of diseases?
2. How prevent pitting in small-pox? Ring worm from spreading?
3. In eruptive fevers, as small-pox, scarlet fever and measles how guard against or prevent?
4. Prevention of scurvy.
5. What preventive measures can we take to check the spread of venereal diseases?
6. Give the means of propagation and the preventive measures in typhoid fever.
7. Can ophthalmia neonatorum be avoided and what would be your method of prevention?
8. What preventive measures can you suggest for cerebrospinal meningitis?
9. Who appoints the health officers, state, county and city, and what qualifications are required?
10. Diarrhea and dysentery, how caused and can they be prevented?

MATERIA MEDICA

1. What is an acid? Composition of Dover's powder.
2. What are agents employed as cathartics.
3. What are agents employed in the treatment of disease called?
4. Through what medium is the influence of medicine exerted on remote parts of the body?
5. How does the time of administering medicines modify their action?
6. Name three effective emetics.
7. What drugs cause eruptions of the skin?
8. What are the medicinal uses of alcohol and what effect have they on diseased conditions? Do you employ them, if so why?
9. What are the uses of narcotics? Name the principal ones.
10. Give the maximum dose for an adult, of strychnine, sulphur, atropia, chloral, morphine, pilocarpin.

MEDICAL JURISPRUDENCE

1. (a) What are the duties of the State Board of Medical Examiners of the State of North Dakota? (b) What does the statute of this state command that the recipient of a license from this board to practice medicine and surgery in this state shall do with it? (c) What is the penalty, if any, for practicing medicine in the state without first obtaining license from this board? 2. (a) What is medical expert testimony? (b) On what is it generally based? (c) Who is competent to give it? (d) Should a physician and surgeon hesitate to give expert testimony, in a worthy cause and after careful preparation on the issue involved? 3. A young woman, pregnant two months, in company with her parents, the man responsible for her condition, and the states attorney of the county in which they all live, called on a physician in this state and requested him to abort her. All agreed that from a social standpoint it was for the best interests of all concerned that the physician comply with the request, and each and all further premised in writing that no matter what the consequences might be, the physician should be excused from civil and criminal liability. The physician complied with the request. She rapidly recovered and all interested were pleased. The physician received \$500. Was he guilty of a crime under the laws of this state? If so what is the punishment? If you answer in the affirmative give your reasons. 4. A regularly licensed physician and surgeon is called by a farmer 15 miles from the physician's office and in the country, at 2 o'clock in the morning. At the time there was a heavy downfall of cold rain. The roads were bad, but not impassable. The physician is supplied with a rig suitable and convenient with which to make the trip. The farmer tells him his wife has suffered an injury by accidentally falling from a mowing machine in front of the knife, and that a limb was severed at the knee; that the wound was bleeding profusely and it seemed impossible to stop it. The farmer was a tenant and without any means whatever, and unable to pay the doctor then or in the immediate future, which fact the doctor well knew. There was no other physician within 50 miles of the farmer's home. The doctor refused to respond to the call and go to the relief of the suffering woman, solely on the farmer's inability to pay him for his services and because it was raining. The farmer was unable to get into communication with any other physician and the woman survived 20 hours, when she died of hemorrhage and blood poison. A post mortem was held and 5 competent and creditable physicians declared that if the woman had had medical attendance within nine hours after the accident she would have survived. Was the doctor guilty of any crime under the law of this state? If so what was it, and what is its punishment? Would a civil action lie against him for damages on behalf of the surviving husband? 5. (a) What is malpractice? (b) What degree of skill does the law require a physician and surgeon to exercise in the practice of his profession? (c) What is the statutory limitation of the prosecution of an action against a physician and surgeon for damages account malpractice in this state?

DISEASES OF WOMEN AND CHILDREN

1. Symptoms, subjective and objective retroversion uteri, treatment of same.
2. Pelvic hematocoele, symptoms, causes and treatment.
3. Symptoms, subjective and objective of laceration of cervix uteri of long standing.
4. Symptoms and complications of gonorrhea in female.
5. Dysuria in female, causes and treatment.
6. Symptoms and treatment capillary bronchitis.
7. Causes and treatment enuresis.
8. How feed an infant of three months deprived of mother's milk?
9. Treatment of enterocolitis.
10. Treatment of pertussis.

NERVOUS DISEASES

1. Differential diagnosis of cerebral hemorrhage and tumor.
2. What is myxedema? Give symptoms and treatment.
3. Define migraine. Give causes, symptoms and treatment.
4. How would you treat a case of delirium tremens?
5. Symptoms, prognosis and treatment chorea.
6. Infantile paralysis; (a) What part of cord is involved? (b) Give symptoms and treatment in full from the onset.

SURGERY

1. How would you diagnose a subcoracoid dislocation? Name method employed in its reduction, with the different steps in the operation.
2. Give your treatment in detail for fracture of humerus just above the condyles.
3. Give your method of treatment for a nail wound of foot.
4. Differential diagnosis of intracapsular fracture and dorsal dislocation of head of femur and give your treatment for this fracture in a woman 70 years of age.
5. How would you diagnose a case of complete inguinal hernia from a hydrocele, and describe the radical cure for hydrocele.
6. Describe in full Bassini's method of operation for the radical cure of hernia.

Rhode Island July Report

Dr. Gardner T. Swarts, secretary of the Rhode Island State Board of Health, reports the written examination held at Providence, July 7-8, 1910. The number of subjects examined in was 7; total number of questions asked, 70; percentage required to pass, 80. The total number of candidates examined was 10, of whom 6 passed, 3 failed and one withdrew. The following colleges were represented:

College	PASSED	Year Grad.	Per Cent.
College of Physicians and Surgeons, Baltimore		(1909)	81.1
Tufts College Medical School		(1910)	84
Boston University		(1899)	80.3
Columbia Univ., College of Phys. and Surg.		(1878)	80
Jefferson Medical College		(1908)	83.3
University of Vermont		(1910)	82.9
	FAILED		
Baltimore Medical College		(1909)	77.5
University of Maryland		(1910)	69.9
Laval University, Canada		(1905)	72.5

Medical Economics

Insurance and Industrial Cooperation for the Promotion of Public Health

The importance of systematic and widespread efforts for the improvement of public health are evidently appreciated by the insurance interests—both the old-line and the fraternal organizations. A number of the leading old-line companies have inaugurated campaigns among their policy-holders with this object in view. In a recent number of the *Metropolitan*, an insurance publication, appear articles on flies, the refrigerator, etc., as well as a reproduction of the now celebrated poster originated by the Florida Board of Health showing, with graphic but wholesome unpleasantness, the manner of life of the ordinary house fly.

An insurance company sent to its policy-holders a pamphlet on "Living and Sleeping in the Open Air," prepared by Dr. Thomas S. Carrington, assistant secretary of the National Association for the Study and Prevention of Tuberculosis. This pamphlet contains plans and photographs for sleeping porches and shelters adequate for use on roofs and in back yards. The details will make it easier for many persons to secure places for out-door sleeping.

Another company has issued a number of bulletins prepared by the Policy Holders' Health Bureau, established to assist in guarding the health and lives of the policyholders. One bulletin deals largely with the influence of alcohol on the death rate and the dangers of the use of alcohol as a beverage. Obesity, the hookworm disease, sanitary neglect in rural districts and hygienic hints for winter and early spring are also considered. Another is devoted largely to the dangers of "patent medicine" and the folly of self-drugging. Narcotic drug habits, hygiene of the mouth, malaria, yellow fever and health hints for hot weather are also considered.

The *Western Review*, a monthly journal devoted to the interests of fraternal benevolent societies, has established a "Department of Public Health," under the supervision of the medical director of one of the societies and has made this department a feature in several of its recent numbers.

A shoe company has issued a vest-pocket book "for the welfare of its employees," which praises the Safe and Sane Fourth idea, gives the text of the Massachusetts law on the subject, and supplies terse directions for treating Fourth of July accidents. For good measure instructions on the prevention of tuberculosis are added, and attention is called to the privilege of examination by the company's physician and of being cared for in a free bed which the company maintains at a certain hospital.

The increased attention paid to public health matters by business interests is of especial significance as it is an evidence of general recognition of the wastefulness of preventable sickness and disease and the economic value of good health.

Book Notices

DIE EXPERIMENTELLE PHARMAKOLOGIE ALS GRUNDLAGE DER ARZNEIHANDLUNG. Ein Lehrbuch für Studierende und Aerzte. Von Dr. Hans H. Meyer und Dr. Gottlieb, Professoren der Pharmakologie. Paper. Price, 12 marks. Pp. 483, with 62 illustrations. Berlin: Urban & Schwarzenberg, 1910.

This collection of the data of experimental pharmacology from the standpoint of medical practice forms a noteworthy contribution to pharmacology and treatment. While pharmacology from the point of view of pure science is to be regarded as a section of biology, from the medical point of view it is an applied science and finds its justification as a vital part in the equipment of the modern physician only when it considers the action of drugs in relation to the disease processes. Such a consideration necessitates an adequate fundamental conception of the normal physiologic processes and the manner in which they may be influenced by drugs, an understanding of the alterations in the normal which constitute the pathologic, and wise judgment in correlating drug-action with these altered processes. The task of correlating the data of pharmacology and pathology with the view of providing a rational basis of drug therapy is one of extreme difficulty.

In this work the authors adopt a classification of drug actions into two groups, organotropic, i. e., action influencing function, and etiotropic, i. e., action on causes of disease. As illustrating the present development of the science it is interesting to note that the greater part of the book is devoted to drugs possessing organotropic action. The consideration of these is subdivided, according to the function chiefly affected, into sixteen chapters. These include the pharmacology of motor nerve-ends, of the central nervous system, of sensory nerve-endings; of the vegetative (involuntary nervous) system, of the eye, of digestion, of uterine movement, of the circulation, of respiration, of renal function, of sweat secretion; of metabolism, of muscles, of the blood, of the heat-economy and of inflammatory processes. The consideration of etiotropic drugs is included in one chapter, which takes up the general antiseptics, specific antiseptics and concludes with a brief outline of serum therapy.

This method results in the concentration of the attention on the physiologic process under discussion. Nearly every chapter begins with a concise exposition of the physiology involved. The action of the drugs which affect the function is described and explained, and finally the alterations of the process in disease and the connection of the drug-action with this are indicated. The physiologic considerations are concise, illuminating and decisive; more dogmatic than would be allowable in a treatise on pure physiology. It is worthy of note that in many instances the reaction of an organ to drugs throws important light on the mechanism of its function, and in this respect the authors have contributed materially to physiology by pointing out such cases.

A short general chapter on the relation of drug-action to the vegetative nervous system is of great service in understanding the action of drugs on the particular organs controlled by it. The action of drugs on metabolism is presented only in outline, but the state of development of that field of pharmacology is such that its consideration is of necessity schematic; but there is left in the mind of the reader a clear, general conception of the effects produced by such drugs as iodids, phosphorus, arsenic, etc., which heretofore have so often been relegated to the mysterious realm of "alteratives." The discussion of circulatory conditions in which drugs may be indicated, and their rational application, is carried out under three broad headings—cardiac insufficiency, cardiac and vasomotor paralysis, and vascular spasm. One could wish that the authors had considered more specifically the nature of pathologic processes. It is evident that they regarded only broad discussions in this relation as within the scope of the book.

One might wish for a fuller explanation of the effects of such drugs as atropin, cocaine and bromids on the central nervous system. Differences of opinion will arise as to some of the conclusions drawn; e. g., as to the identity of action of nicotin and pilocarpin on the heart, the action of morphin on sensory nerve-ends, the action of calomel in causing diu-

resis, etc., but one feels that the explanations advanced require serious consideration. It is disappointing to find American work so scantily represented, and it is difficult to believe that this is the result solely of lack of worthy research by American investigators. The discovery of anesthesia by subdural cocain injection is ascribed to Bier; no mention is made of the astonishing results on resuscitation obtained by Crile; of Sollmann's work on the kidney; of Embley's (English) work on the effects of chloroform on the inhibitory cardiac center, etc. On the whole, however, the references to the literature are a valuable and satisfactory feature of the work. The data regarding drugs, being grouped about the consideration of function, have received the logical arrangement, but at the inevitable cost of a scattering of information regarding any particular drug. To cite a single instance, the action of morphin is separately considered in eight different chapters. The toxicology of various drugs, and the preparations in which drugs are available, are given subordinate and sometimes anomalous place in this scheme. This does not affect the value of the book in its broadest application; but does limit its usefulness as an instrument of teaching in this country, at least. The student would find difficulty in getting from it a broad, consecutive understanding of all pharmacology, but the study of the book after a preliminary training in this subject according to our present methods, would make such training vital in the study of the treatment of disease.

MEDICAL ELECTRICITY AND RÖENTGEN RAYS. With Chapters on Phototherapy and Radium. By Sinclair Tousey, M.D., Consulting Surgeon to St. Bartholomew's Clinic, New York City. Cloth. Price, \$7 net. Pp. 1116, with 750 illustrations. Philadelphia: W. B. Saunders Co., 1910.

In this work the author has undertaken to cover completely the subjects of the therapeutic and diagnostic uses of electricity, and Roentgen rays; not content with this he goes even beyond his title, and considers also the uses of radiant heat and radium. The work is an enormous mass of detail. The physics of electricity, as bearing on the medical uses of the agent, first comes in for extended consideration—over 250 pages. With this there is a very full description of apparatus. Then are given—not enumerating all topics—physiologic effects of electricity, electropathology, electrodiagnosis, ionic medication by electrolysis, physiologic and therapeutic effects of electromagnets, electricity in diseases of the nervous system, and high-frequency currents; to each of these is given a chapter or more. Phototherapy, x -rays with all of their apparatus and uses, and finally radium are then considered. One can hardly look in the vast fields for a topic which the author has not considered, but the inexperienced reader will find more difficulty in getting systematic instruction from the work than he will in getting isolated facts. Everything is given, without a sense of perspective as to the relative value of different parts, and the parts of the work are of very unequal merit. The consideration of apparatus, of electricity and x -rays in diagnosis are good; the therapeutic parts are much less satisfactory and are not, in our belief, a conservative guide.

THE DISEASES OF THE NOSE, MOUTH, PHARYNX AND LARYNX. A Text-Book for Students and Practitioners of Medicine. By Dr. Alfred Bruck (Berlin). Edited and Translated by F. W. Forbes Ross, M.D., Late Civil Surgeon, His Britannic Majesty's Guards Hospital, London. Assisted by Friedrich Gans, M.D. Cloth. Price, \$5. Pp. 615, with 217 illustrations. New York: Rebman Company [1910].

This book has been written to meet the needs of the general practitioner. Each of the four subjects is divided into a general and a special section, the former dealing with the anatomy, physiology, methods of examinations and general therapy, the latter dealing with the diseases pertaining to the subjects under discussion. The anatomic descriptions cover the essential points and are accompanied by good illustrations. The methods of examination are discussed in a way that will appeal to the general practitioner, who has not had special training in these fields. In dealing with the treatment of the different diseases, special emphasis has been laid on procedures that may be used by those who have not had the opportunity to become schooled in the technic of the more difficult operations. The arrangement of the material of this work is systematic, and the discussions are clear and concise, meeting admirably the needs of men in general practice.

Medicolegal

Giving Medical Treatment for Eyes, Practice of Medicine—Admissibility of Evidence—Advertising—Claiming to Be an "Ophthalmologist" No. Defense

The Kansas City Court of Appeals says that the evidence in the case of *State vs. Blumenthal* (125 S. W. R., 1188), tended to show that the defendant had an office in a hotel, and that on his door was the sign, "Dr. H. M. Blumenthal;" that a woman went to his office and engaged him to treat her eyes, he telling her that she had a cataract, astigmatism, and other ailments of the eyes, which he treated by prescribing ointments or salves and eyewashes, for which he charged her \$10; that he likewise furnished and fitted eyeglasses, for which he charged \$15. The eye medicine was sent to her by her brother at one time and delivered personally by the defendant at several other times. In view of such evidence, there can be no doubt that the defendant was practicing medicine within the meaning of the law.

It was decided by the Supreme Court of Illinois (*People vs. Smith*, 208 Ill., 31) that a traveling optician who invited persons, by advertisements, who were afflicted with dizziness, neuralgia, etc., to visit him and obtain relief by purchasing spectacles, and disclaimed medical or surgical treatment, was not treating, operating, or prescribing for physical ailments under the statute of that state. That was no more than to say that one who merely sold and fitted eyeglasses was not practicing medicine, and the trial court gave such declaration of law in this case. But the facts which the evidence tended to prove against the defendant in this case were that he not only sold and fitted spectacles, but gave medical treatment for the eyes.

Objection was made to the admission of the evidence showing the sign at the defendant's room door at the hotel, as set out above, but the ruling was proper. It tended, connected with the other evidence, to support the charge made.

The trial court likewise properly admitted evidence of the defendant advertising as a practitioner of medicine. It is true that the Missouri statute constitutes the act of advertising as a physician as an offense within itself, yet that fact does not exclude the fact as probative of the offense of practicing. The fact that evidence having a tendency to prove the offense charged may also tend to prove some other offense not charged does not necessarily render it incompetent.

There was some claim made by the defendant that he was an ophthalmologist. If that be accepted as true, it would not serve him any purpose since that is a branch of medical science, and its practice would fall within the terms of the statute. That term seems to signify some disease or diseases of the eye, and the court can see no reason why one who prescribes medicines for such diseases would not be as guilty as by any other name. It is the act committed, and not its designation, which constitutes the offense.

The court was not impressed with the defendant's argument as to lack of proof as to his practicing. His sign, office, advertisement, treatment for a considerable period of the prosecuting witness was ample evidence.

Examination of Body for Defendant in Homicide Case Does Not Create Relation of Physician and Patient, or Privilege

The Supreme Court of Nebraska says, in *Ossenkop vs. State* (126 N. W. R., 72), a homicide case, that, after the homicide, the defendant employed a physician to examine the body of the deceased person and to report the result. Later the same physician was selected by the state to make a post mortem examination. He performed the service and testified at the trial to the conditions disclosed. The defendant contended that knowledge of all of the facts to which the physician testified was obtained as a result of confidential communications properly intrusted to him by the defendant. The point was that the physician's testimony was admitted in evidence in violation of the provision of the statute that no practicing

attorney, physician, surgeon, minister, etc., "shall be allowed, in giving testimony, to disclose any confidential communication, properly intrusted to him in his professional capacity, and necessary and proper to enable him to discharge the functions of his office according to the usual course of practice or discipline." As applied to physicians, the purpose of the statute is to prevent the improper disclosure of secrets or facts learned by means of the confidential relation. The relation protected is that of physician and patient. Outside of that relation the parties are on an equal footing, where the rule of the statute and the reasons of public policy on which it is founded do not follow. In this case the physician was not employed to examine or treat the defendant or any member of his family. The relation of physician and patient did not exist between them. The exhumed body contained no secrets which could be kept within the exclusive knowledge of the defendant and the physician. The means of ascertaining the condition of the body was equally within the reach of the defendant and the state. The court was entitled to know the truth. The purpose of the statute is to protect patients from objectionable disclosures; but it was never intended to shield the defendant in his position. Consequently the ruling of the trial court in admitting the physician's testimony must be approved.

Aider in Abortion Punishable as Principal

The Supreme Court of New Jersey says that it was contended in *State vs. Wilson* (75 Atl. R., 776) that the history of the statute of that state passed in 1872, and now in force, was such as to compel the conclusion that the legislature intended to legitimize the procuring of abortions, or at least to grant immunity to all who knowingly aided or assisted in the commission of such offense. This rather startling proposition was based on the circumstance that the original act of March 1, 1849, contains the words, "and every person with the like intent knowingly aiding and assisting such offender or offenders," which were omitted from the act of 1872. But the court suggests that the legislature may have concluded in 1872 to retain the principal offense only with its legal incidents as to who were to be held as principals in the commission of such misdemeanor. As between this intelligent and officious purpose on the part of the legislature and the imputation to it of an express intention, if not to legitimize, at least to condone one of the gravest offenses against society, the court, as a co-ordinate branch of the government, ought not for a moment to be skeptical. So it is held that if A directs a woman in an early stage of pregnancy—i. e., before the child is quick—to go to B to have a miscarriage produced, which is accomplished by B by the use of instruments, A may be indicted as a principal offender under the New Jersey statute, and, on proof of a concert of action between him and B, may be convicted under the rule that all concerned in a misdemeanor are equally guilty.

- 1 *Hysteria under Psychoanalysis. G. M. Parker, New York.
- 2 *External Urethrotomy without a Guide. C. L. Gibson, New York.
- 3 *Vaccines in Treatment of Bacterial Infections in Infants and Young Children. E. M. Sill, New York.
- 4 *A Theory as to the Origin of Leprosy. J. Atcherley, San Francisco.
- 5 The Genesis of Hysterical States in Childhood, and Their Relation to Fears and Obsessions. T. A. Williams, Washington, D. C.
- 6 *An Unusual Case of Congenital Absence of Anus and Lower End of Rectum. J. Wiener, New York.

1. Hysteria Under Psychoanalysis.—Parker gives a summary of the interpretation of hysteria by the psychology of Janet.

2. External Urethrotomy Without a Guide.—In Gibson's operation an exaggerated lithotomy position is maintained under general anesthesia. The index finger of the left hand passed into the rectum acts as a guide to the membranous urethra. An incision is made in the middle line, the knife being held perpendicularly through the tissues until it enters the well-dilated membranous urethra. A suitable probe is passed along the knife, which is still held perpendicular, the finger having been removed from the rectum. Along this probe or director the stricture is divided. A small urethrotome or bougie is passed toward and through the anterior urethra, and a filiform bougie is entered. The knife is fitted into the staff and pushed home through the stricture, after which an Otis urethrotome is passed and the operation completed by cutting the stricture through. Bladder drainage is instituted.

3. Vaccines in Treatment of Various Bacterial Infections.—Sill treated 49 children with local suppurations with vaccines made from the dead bacteria removed from the patients under treatment. Of these 49 children, all under 5 years of age, 30 were cases of subacute or chronic otitis media. Of these 28 children were cured, 10 improved, and one not improved. The earlier in the discharge the vaccines were used the better were the results. Pneumonia and erysipelas were cured by vaccines. The vaccines were given in doses of from 2 to 8 million bacteria. Other treatment was abstained from.

4. Origin of Leprosy.—According to Atcherley, leprosy is a chronic, diathetic disease, with gradual onset and irregular course, characterized by an inflammatory fibroid degeneration of the nerve tissue generally, which precedes the deposit of the lepra bacillus. This nerve degeneration is the result of defective food pabulum supplied by the blood, from the ingestion of improper food. This theory is based on the fact that the pathologic changes in leprosy bear a striking analogy to those of scurvy.

6. Congenital Absence of Anus and Rectum.—Wiener reports the case of a new-born infant, in whom there was absence of anus and lower part of rectum; an immediate operation, by incision of the perineum, with pushing down of the closed pouch of rectum, and suture, saved the life of the infant.

8. Leukocytes in Pulmonary Tuberculosis.—The authors undertook this study (1) to determine whether the leukocytes in cases of pulmonary tuberculosis in a sanatorium a little above sea level present a constant picture in the various stages of the disease, and in accordance with the improvement or retrogression of the patient; (2) to see what are the average proportions of the different white blood cells in phthisis. They found:

1. The percentage of polymorphonuclear neutrophils was diminished in incipient and moderately advanced cases, being less in the former. It was also diminished in patients who were improving.
2. The percentages of the different forms of polymorphonuclear neutrophils, classified according to the number of nuclei they contained, bore no constant relation to any stage or to the progress of the disease.
3. The percentage of lymphocytes was increased in incipient and moderately advanced cases and in improving patients.
4. The percentage of large mononuclear and transitional cells, grouped together, while within normal limits, was greatest in incipient and in improving cases.
5. The percentage of eosinophils was greatest, though normal, in incipient cases.
6. In moderately advanced cases were found the lowest percentage of large mononuclear and transitional cells, grouped together, and of eosinophils, and the highest percentage of large mononuclear cells.
7. In patients whose condition was stationary occurred the highest percentage of polymorphonuclear neutrophils and the lowest per-

centage of lymphocytes, of large mononuclear cells, and of large mononuclear and transitional cells grouped together.

8. Whenever one extreme was exhibited by moderately advanced cases or by stationary cases the other extreme was furnished respectively by incipient cases or by improving patients. Par-advanced and retrograding cases respectively held a middle position, which approached the condition found in incipient and in improving cases respectively, rather than the other extreme.

9. In addition to the mononuclear basophilic cells, the blood occasionally contains polynuclear basophilic cells, easily distinguishable from other leukocytes.

11. **Concomitant Epigastric Hernia and Gastric Ulcer.**—Fourteen years ago Soper's patient was operated on for hemorrhoids and fistula. Stomach trouble developed soon after. Symptoms were distress and burning sensation accompanied by eructations of gas and acid-tasting liquids, attacks lasting from a few minutes to several hours, and were usually relieved by taking food. Occasional vomiting occurred of very acid mucus and food particles. Patient often had attacks in the early part of the night. These symptoms with remissions and exacerbations persisted. During the past year more severe attacks of pain and vomiting frequently occurred. The abdomen presented very large fat deposit. There was tenderness over the celiac axis and in the median line just below the ensiform cartilage. Gastric ulcer was diagnosed. The pains were absent while a bland diet was followed, always recurring when coarse vegetables or meats were eaten. Operation was advised but refused.

On Nov. 13, 1909, she was seized with a severe attack following a meal of pork and sauerkraut. The epigastrium was very tender to pressure, the hernia extremely so. Despite strict ulcer cure régime the pains and vomiting persisted. On November 26 she was operated on. The hernia consisted of a thin band of the lesser omentum containing a mass of fat about the size of an almond. The stomach was explored and a slightly indurated ulcer of about the size of a silver half dollar was found in the middle of the lesser curvature in the anterior wall. The incision was closed. The patient was kept in bed for four weeks under strict bland diet. Recovery was interrupted by an attack of influenza occurring in January; since then, uneventful. There has been no recurrence of the hernia, pain, or gastric distress.

- 22 *The Relation of the Physician to the Public. T. Brown, Hamilton.
- 23 The Future Policies of the Medical Profession. N. P. Wood, Independence.

22. **The Physician and the Public.**—It is pointed out by Brown that the most important problem concerning the dignity and material welfare of the medical profession to-day is to convince men, women and children that we are striving to be helpful and protect them from the disasters following ignorance, superstition, incompetence and disease; that while physicians live by their work, they still sacrifice for the public service much in their lives that men hold good; that they are seeking after medical truth, and desire the fellowship of all who are working for the same great object. If this were the fixed belief of the public the advice and desires of physicians would be speedily translated into laws regulating the profession and protecting the public health. Physicians would not then plead in vain for securing the higher standard of education, morality and scientific attainments for the medical profession. Protests against the use of preserva-

tives in food products would not be ignored by competent lawmakers. The triumph of the profession in conquering pain, sepsis, smallpox, yellow fever, malaria, diphtheria, rabies; in robbing all the infectious diseases of many of their terrors; in creating a substantial hope for many now tainted with the white plague; developing the astounding successes of modern surgery, would be acclaimed the highest and most useful achievements of mankind.

- 34 The Mechanism of Tone in Plain Muscle. D. J. Lingle, Chicago.

31. **Specific Anesthetic Properties of Magnesium Salts.**—Meltzer and Auer have attributed specific anesthetic powers to the magnesium salts but Guthrie and Ryan explain the effects on the ground that asphyxia is produced, and in the present article they describe further experiments in support of this view. Their principal experiments were made on frogs and lead them to conclude that a very marked early effect of magnesium salts when injected subcutaneously in sufficient doses is a paralysis of the peripheral neuromuscular apparatus of voluntary muscles. An animal in such a condition is sensitive, but ordinarily does not respond to sensory stimulation because it is paralyzed. Paralysis of the more distal skeletal muscles is followed by a gradual paralysis of the respiratory muscles which results in a decrease in the pulmonary ventilation. This, in conjunction with the probable action of the salt on other processes concerned in respiration, produces a state of partial asphyxia manifested by the usual symptoms. Anesthesia may or may not occur at this stage, depending on the degree of asphyxiation. They believe, therefore, that the anesthesia that may follow the infection of magnesium sulphate solutions is due chiefly to asphyxia. Magnesium salts cannot be regarded as having marked specific anesthetic properties.

32. **Relation of the Pancreas to Blood Diastases in the Dog.**—The work of Otten and Galloway indicates that the source of the diastases in the blood is not exclusively in the pancreas. That the pancreas plays an important rôle in the production of the diastases or in their destruction, is indicated by the fact that after removal of the pancreas, there is a markedly diminished concentration of the diastases in the blood which does not keep pace with the progressive marasmus nor correspond to the state of nutrition or kind of food. This concentration approaches a constant level, neither falling below a certain point nor returning to normal. Since the concentration of the diastases in the blood and in the lymph does not seem to parallel the hyperglycemia and diabetes after pancreatectomy, the diastatic ferments, as Schlesinger has pointed out, seem to have no direct relation to sugar metabolism, and as Carlson and Luckhardt suggest, appear to be waste products. It may be, however, as Schlesinger considers, that in some mammals the main bulk of the blood diastases are pancreas diastases reabsorbed from the external

secretion. If this is so, then on removal of the pancreatic factor, the blood and lymph diastases remaining would be those of the liver and other tissues, such as the intestinal mucosa, and possibly the leukocytes. Two factors must then be considered in connection with the diastases of the blood. First, the diastases of pancreatic origin, exogenous in a sense, and of no significance in carbohydrate metabolism; and second, endo-enzymes, possibly largely from the liver, which before leaving the tissue cells may play an important rôle in the destruction of glycogen.

33. **Resistance of Rats to Morphin Poisoning.**—Hunt found that after thyroid feeding, rats and mice are less resistant to morphin poisoning than before. According to Olds, thyroidectomized rats show the same resistance to morphin poisoning as normal rats, at least, within a period of from 8 to 28 days after the operation. These facts seem to question or at least limit the Hunt test as a test for the concentration of thyroid secretion in the body fluids.

44. **Cholecystitis Simulating Typhoid.**—Prince adds two cases to three previously published. In the first case the symptoms led to the diagnosis of perforation of the intestines. An incision was made in the median line and the small intestines rapidly examined, which showed no symptoms of perforation. The gall-bladder was then examined by palpation and found very much distended. Eight or ten stones were removed and some bile was discharged after the first flow of pus. In the second case a diagnosis of typhoid complicated by cholecystitis was made. The gall-bladder contained clotted bile.

50. **Decomposition of Tyrosin.**—The decomposition of tyrosin has attracted considerable attention because of the fact that it is the precursor of homogentisic acid which appears in the

urine in alkaptonuria. It has been claimed that homogentisic acid is an intermediary step in the normal catabolism of tyrosin and the similar compound phenylalanin. Those who maintain this view consider that alcaptonuria is simply due to a failure of the organism to oxidize the homogentisic acid formed. Dakin attempted to determine this question by administering a compound of tyrosin, and found no evidence of the formation of homogentisic acid. In further experiments with the administration of inactive tyrosin in such quantities that some of it appeared unchanged in the urine, no homogentisic acid could be detected, so that the author concludes that this substance is not a necessary step in the metabolism of tyrosin.

- 86 Practical Method for the Preparation of Phenolsulphonephthalein. E. A. Slagle, Baltimore.

85. Functional Activity of the Kidneys.—In all, over 200 functional tests with phenolsulphonephthalein have been performed by Rowntree and Geraghty on 150 different subjects. In normal cases the drug appears in the urine in from 5 to 10 minutes, and 40 and 60 per cent. of the 6 gm. dose, the average being about 50 per cent., is recovered in the first hour. From 15 to 25 per cent. of the drug administered is recovered in the second hour, making the total recovery for two hours from 61 to 85 per cent. The authors do not consider the time of total elimination as of so much value as the amount of elimination for a definite period. The time of appearance of phthalein in the urine is from 5 to 10 minutes when the secretion of urine is free, but even in health this may be delayed when the secretion is very scanty. Following its appearance the intensity rapidly increases and reaches its maximum in from 15 to 20 minutes. At the end of from an hour to an hour and a half, as a rule, an appreciable decrease in the density becomes manifest. A tapering diminution occurs from the end of the first hour. At the end of the second hour only a definite pink is obtained on addition of an alkali. In the majority of instances excretion is practically complete at the end of two hours. The application of this test in the various types of nephritis has given the following results:

In 3 cases of acute nephritis no increased permeability of the kidney has been demonstrated, but in 2 out of the 3 cases a marked decrease in the amount of elimination has been observed. In 8 cases of parenchymatous nephritis with one exception there has been a marked decrease in the amount excreted. In one case only 10 per cent. was excreted in two hours. The greatest decrease has been noted in cases in which clinically marked secondary sclerotic changes were considered to be present. In 10 cases of chronic interstitial nephritis a low output was encountered in each instance, the decrease being usually proportionate to the degree of severity of the disease as estimated clinically. In 2 cases only a trace of the drug—less than 1 per cent.—was eliminated in the course of an hour. Both patients died of uremia within 2 months. In 60 cases with obstruction in the lower urinary tract, almost all being patients with hypertrophy of the prostate, the phthalein test has given valuable information. As a rule, the test has demonstrated the greatest impairment of function in those cases which have large residual urine and have not been leading a catheter life. In many instances in which the output of the drug was low when the patient was first seen, adequate regimen has resulted in a decided improvement of the kidney function as indicated by the test. When the time of appearance is delayed beyond 25 minutes and the output of the drug is below 20 per cent. for the first hour, operation is postponed regardless of the patient's clinical condition. If, under routine treatment, the output remains low but constant, the renal function is probably in a stable condition and the operation may be undertaken, care being taken to select an anesthetic which will not further depress the renal function. In one instance, a successful operation was performed with an output of 8 per cent. for the first hour, but this output had remained constant for a period of 5 weeks. The low output here was ascribed to chronic interstitial changes in the kidney, and nitrous oxid was accordingly employed. Repeated determinations should be made, and except when unavoidable, operations should not be performed when the tests indicate a decreasing function. Again, when only a trace of dye is excreted operation should not be attempted, as grave renal changes exist.

The test has made it possible, the authors declare, to select a time for operation when the kidneys have regained their full functional power and stability. In no case in which the functional test indicated an efficient or stable renal function prior to operation, has any evidence of renal inefficiency

become apparent subsequently. The authors conclude that phenolsulphonephthalein itself is better adapted for use as a functional test than any other drug previously employed for the same purpose on account of its early appearance in the urine and the rapidity and completeness of elimination by the kidney.

2. Epilepsy.—There is no single specific remedy in the treatment of epilepsy, says Turner, although the alkaline salts of bromin come nearest to this definition. But the influence of the bromids on epileptic convulsions is variable and uncertain. In the first place, bromid medication may arrest the seizures immediately, or within a short period of their administration, temporarily or permanently. Second, the bromids may induce a lessening in the severity and frequency of the seizures. Third, the bromids may exert no influence at all on the disease, or may even augment the frequency or severity of the seizures. Under the influence of the salts

of bromin a considerable number of cases of epilepsy are temporarily "cured" or materially improved. Bromid treatment should be commenced at the earliest possible time after the onset of the fits. If benefit does not follow a daily dose of from 45 to 75 grains of one or a combination of the bromid salts, some other remedy or method of treatment should be sought for and applied. Turner holds that the large doses sometimes prescribed—from 100 to 150 grains daily—although no doubt suppressing the seizures for a time, induce other and more serious phenomena.

Of the combinations of the bromids with other remedies Turner has found Gelineau's formula the most useful and satisfactory. It is prescribed in the form of dragées, containing 1 gram of potassium bromid, $\frac{1}{4}$ milligram of picrotoxin, and $\frac{1}{2}$ milligram of the arseniate of antimony. He has used the dragées in all forms of epilepsy with considerable success. The method of prescribing them is simple: One dragée to be taken either during or immediately after a meal thrice daily for a week, an additional dragée being added weekly until the patient is taking 4, 5 or 6 per diem. Turner has found 6 dragées a day usually sufficient to hold the fits in check, although according to Gelineau as many as 10 or 12 may be taken daily. In patients with confirmed epilepsy with mental deterioration the use of bromids is of relatively little value. Their continued administration in these cases does, however, produce a diminution in the number, and perhaps in the severity, of the seizures.

5. *Dermato-Myositis*.—The case reported by Gwynn and Gordon seems a fairly typical one, but presents no new features and affords no fresh clue to the etiology. The clinical picture suggested a toxemia arising from some infection of the alimentary canal, and efforts were therefore directed to disinfection of the mouth, throat, stomach and bowels.

8. *Tuberculosis and the Generative Functions*.—Davison points out that Koch's bacillus can only successfully invade organisms which lack proper defense; we know that the lines of natural defense are weakened when the organism loses its vigor; we know that sexual functions exercised in immediate degree, or exercised by organisms in a state of degeneration, spend inordinately the strength of the individual. Finally, we know that modern hygienic measures snatch from a sure death many children who afterward pass on to the reproductive epochs of life with frail organisms. This simultaneous occurrence of the great sexual activity, or sexual activity exercised under disadvantageous conditions (maturity in both sexes and advanced maturity in the male), and great mortality from tuberculosis cannot, therefore, be a mere coincidence—the first must be the cause of the second.

10. *Treatment of Rheumatism by Bee-Stings*.—Maberly reports several cases of chronic, apparently intractable cases of rheumatism which were cured to all intents and purposes by being exposed to bee-stings at regular intervals. One, a man about 35 years of age, had been laid up three times with rheumatic fever for 6 or 7 months each time, and found his joints increasingly stiff with each attack. In his case the bee stings did marvels. His feet had always been stiff from the first attack, but now he could walk anywhere and "did" about 20 miles every Sunday. His ankle movements were perfect and he stood on his toes quite easily. He says that he always ate and drank what he liked, and whenever he could catch a bee in his garden he did so and put it on. Maberly saw a number of other cases, some of old-standing chronic rheumatism, both in elderly and younger subjects, and all were doing well, while in nearly all the usual remedies had been tried without any good results.

12. *Tubercle Bacilli in the Feces*.—Altogether 109 different specimens were examined by Philip and Porter. Of these, 99 were from patients suffering from pulmonary tuberculosis, in different stages of the disease. None of the patients had intestinal tuberculosis. The other specimens were from one case of tuberculous peritonitis and from patients without a suspicion of tuberculous infection. Of the 109 patients, only 34 had sputum in which tubercle bacilli had been discovered; 42 had sputum in which no bacilli were found, and 24 had no sputum whatever. Of the 100 tuberculous patients examined, 79 were found to yield tubercle bacilli, and only 21 were negative. Of the 9 specimens from presumably normal subjects none yielded tubercle bacilli. Of the tuberculous patients all those with bacilli in the expectoration, with one exception, presented tubercle bacilli in the feces. Of the 42 patients in whom bacillary examination of the sputum was negative, 29 gave tubercle bacilli in the feces. Of the 24 without sputum, 17 showed bacilli in the stools.

Philip and Porter claim that the occurrence of the tubercle bacilli in the feces is independent of the presence of an intestinal lesion. Indeed, their presence has little reference to abdominal tuberculosis. They were actually absent from the only case of tuberculous peritonitis which was examined. The remarkable frequency of their occurrence in relation to pulmonary tuberculosis, not only in cases in which tubercle bacilli were determinable in the sputum, but also in cases in which either bacilli were absent or there was no sputum whatever, would seem to afford an important addition to their means of diagnosis in doubtful cases of pulmonary tuberculosis.

13. *Neurogenic Coordination of Heart Impulse*.—Kronecker's observations show that the coordination of the different parts of the heart is brought about through a nervous channel.

14. *Mongolian Imbeciles*.—The authors examined 28 patients corresponding to 56 eyes. Nineteen patients had lens changes (67.8 per cent.); 18 had typical lens changes (64.3 per cent.); 35 eyes had cataract changes of some sort (62.5 per cent.); 33 eyes had typical changes in the lens (58.9 per cent.); 10 patients had some inflammation of the lids (35.7 per cent.); 7 patients had squint; 4 had chorioidal changes, and 2 had nystagmus. The age of the youngest patient was 5 years and the oldest 43. The youngest showing cataract was 9 years, and the oldest patient had a well-developed typical cataract of the kind described. Fourteen patients had the interpalpebral fissure directed upward and outward.

17. *Recurrent Monstriparity*.—The patient, aged 35, a strong, healthy woman, gave birth to a full time female child having a large cephaloceles presenting from the vertex. The first pregnancy went to term, when a normal male child was born. The second pregnancy ended in abortion at the end of the third month; the fetus was anencephalic. The third pregnancy ended in abortion at the fifth month; the fetus (male) was anencephalic. The fourth pregnancy concluded at term, and is the subject of the present report.

18. *Treatment of Typhoid Fever*.—Arnold says that none of the various methods of treatment have hitherto been successful in definitely controlling the course or limiting the duration of typhoid fever. A measure employed at the Civil Hospital, St. Helena, during the past 4 or 5 years, has resulted in a distinct shortening of the average duration of illness, and in a remarkable amelioration of all the symptoms. This particular measure consists in the administration by the bowel of turpentine and olive oil from the first day of treatment, and its regular use at stated intervals until the temperature has been normal for at least ten days. When the case first comes under observation an enema of turpentine 5j and olive oil Oj is given by a funnel and tube. The foot of the bed being well raised, the emulsion is allowed to find its way slowly up the bowel. On the next day, or the day after, the same quantities are repeated. A preliminary thorough cleansing of the bowel by a dose, or preferably small divided doses, of calomel, followed by castor oil, prepares the ground for the action of the turpentine.

37. Improved Death Certificates.—The mayor of Hyères in Southern France is a physician, and a double perforated certificate blank is in use there, to obviate the necessity for informing the friends of the cause of the death. Both blanks are filled out at the same time. The first is to be given to the family to be handed to the authorities as the death notice, and records the name, sex, age, residence, profession, date and physician's signature. The twin certificate records sex, age, married or single, profession, date of death, cause of death and the signature of the physician. The patient's name is not given in this certificate which the physician seals and mails to the mayor. When it is received at the city hall it is deposited in a special locked urn and this urn is opened and the contents officially examined and recorded only once or twice a year. There is thus nothing to conflict with the obligation of professional secrecy, the cause of death not accompanying the name of the individual, but all other details necessary for vital statistics are duly recorded. This system has been in use for nearly two years at Hyères and the workings have been exceptionally satisfactory.

38. Cause of Gin Liver.—Lancereaux has been conducting experimental research for years, the conclusions of which are that cirrhosis of the liver of this type is the result of the action of substances used in wine, beer, etc., for their preservation, especially potassium bisulphate. He was able to produce the typical lesions of gin liver by feeding animals with this salt. The other salts of potassium did not seem to cause disturbances of this kind.

39. See Paris Letter, July 30, page 413.

41. Incomplete Form of Coxalgia.—Kirmisson has encountered 5 cases of a hip joint disease which is distinguished by

lack of severe local symptoms and yet it entails extensive destruction of the joint. A little pain and slight limping were the maximum of the disturbance. In such a case described in detail, a boy of 11 showed no signs of vicious attitude and walking was not painful, but the joint seemed to be unusually relaxed, the condition resembling congenital dislocation. After the trouble had lasted about a year without any aggravation of symptoms, radioscopy revealed extreme atrophy of the head of the femur; it had almost disappeared, explaining the special form of the lameness. At each step the head slipped up on the ilium. Nothing except radioscopy would have suggested such extensive lesions. In another case the youth complained of his knee and limped a little; nine months later atrophy of the muscles on the same side was noticed. The limb was in slight abduction with outward rotation but no pain except when the hip joint was completely flexed. The general condition was good but radioscopy revealed manifest lesions in the head of the femur. In none of the 5 cases reported was there any difference in the length of the legs. In 1 case the symptoms were banished by extension but after an intercurrent measles the hip trouble returned and its tuberculous nature became manifest. As this form of hip joint disease develops so insidiously, it is liable to be confounded with coxa vara.

52 Modified Catheterization of the Ureters. (Nouveau procédé de cathétérisme urétéral.) M. Guéin.

43. Resection of the Rectum with Continent Sphincter.—Desjardins introduces into the rectum a hard-rubber cylinder with cross-bar handle; the diameter is nearly that of the rectum and a deep groove is cut just below the rounding tip. Through an abdominal incision the rectum above the lesion is tied to the cylinder, the thread drawn into the groove. The abdomen is then sutured and the rectum, fastened to the cylinder, is then drawn out through the anus. The lesion can thus be resected outside the body. The protruding stump of the bowel is sutured to the anus just above the sphincter. The results have been complete recovery in two cases of cancer removed by this technic. In another case the cylinder was a straight one and the operation failed; since then he uses a curved cylinder that fits perfectly into the rectum. One of the patients operated on rides horseback now without any disturbances.

45. Pleurisy and Hydrothorax with Heart Disease.—The practical conclusions of this study of effusion in the pleura in the course of heart disease emphasize the importance of relieving the heart by prompt evacuation of the fluid as any effusion in the pleura imposes extra work on the heart.

48. Kaolin Technic for Functional Tests of the Stomach.—Meunier found that the various tests in vogue for estimating the functioning and functional capacity of the stomach all failed to yield reliable findings on account of the fact that the contents of the stomach do not blend to form a homogeneous mass but lie in layers. A portion of the stomach content taken for examination will give entirely different findings according to the spot from which it was taken. All this can be remedied, he states, by having the patient ingest

a suspension of kaolin or fuller's earth, 10 gm. in 100 c.c. of water, before the stomach contents are to be withdrawn. This forms a suspension with the stomach contents, and he aids in blending it by blowing in a little air with the sound just before withdrawing the stomach contents after the test meal. The stomach content thus withdrawn forms a milky suspension entirely homogeneous and with this the various tests are applied as under other conditions. As the amount of kaolin in each c.c. is known, evaporating a given amount of stomach content and calcining it leaves an ash which is practically nothing but kaolin, and from the amount of this in a given amount of stomach content it is easy to deduce the total volume of the latter.

49. **Syphilitic Pleurisy.**—Roger reports two cases of apparently typical pleurisy but the positive Wassermann reaction, the absence of albumin and of tubercle bacilli in the effusion, the negative results of inoculation of guinea-pigs and the rapid recovery under mercurial treatment, all confirmed the assumption of a syphilitic process in the pleura. In four other patients with tuberculous pleurisy but scanty pulmonary manifestations, the reaction for albumin in the sputum was always positive. He refers to two other recently published cases of tertiary syphilitic pleurisy; the Wassermann reaction was positive in both effusion and blood serum, and recovery was soon complete under mercurial treatment.

July 20, XXX, No. 29, pp. 337-348

53 *Clinical Forms of Amyotrophic Rheumatism. M. Klippel and M. P. Weil.

54 *Distant Signs of Abdominal Cancers. F. Lejars.

53. **Clinical Forms of Rheumatism with Amyotrophy.**—Klippel and Weil call attention to the form of polyarthritis with ankylosis and such a degree of muscular atrophy that the latter may be said to dominate the clinical picture. In some cases only one joint is affected and the atrophy is restricted to this limb. In Deroche's case the ankylosis of the shoulder, elbow and hand was followed in less than 5 weeks by atrophy of the entire arm. They are inclined to ascribe the atrophy and also the joint trouble to some change in the axis-cylinder, especially as painful spasms, edema and fibrillary twitching in the muscle were frequent in their two cases on a gonorrheal basis. They review the literature on the subject in detail.

54. **Remote Signs of Abdominal Cancer.**—Lejars discusses the enlargement of the supraclavicular glands and the patch of induration in the pouch of Douglas and the tough shrivelling of the umbilicus as instructive signs of internal cancer. The ovary is a frequent location for transplantation metastasis of gastric or intestinal carcinoma, and the same effect of gravity is seen in the pelvic deposit in the pouch of Douglas. It is equally important to examine the umbilicus, induration and shrivelling at this point sometimes being the first clue to cancer within. In one such case, a robust man of 53 had complained of a little discomfort in the umbilicus and occasional slight pain. Otherwise he was in apparent perfect health, free from any gastro-intestinal disturbances. The umbilicus looked like orange skin, and there was induration but none beyond or below. Lejars diagnosed a deep latent cancer and this was confirmed by the death of the patient from cachexia in less than a year. In another case the umbilicus was apparently normal except that one side had retracted and palpation showed a small nodule below. There was suspicion of gastric cancer in this case and this finding in the umbilicus hastened operative treatment. It is possible that the secondary umbilical cancer may be taken for a hernia or an umbilical hernia may develop a cancerous nodule.

55. **Treatment of Syphilis with Ehrlich's "606."**—The main points in Wechselmann's communication were mentioned in the Berlin Letters of July 23, page 326, and August 13, page 609.

56. **Test Injection of Mercury in Syphilis.**—Glaser reasoned that with a positive Wassermann reaction but no apparent manifestations of syphilis, an injection of mercury might destroy enough of the spirochetes to release endotoxins and cause fever from their absorption. He has consequently applied this test injection as a diagnostic measure and found the febrile reaction a delicate and reliable index. He gives a few typical curves to show the abrupt rise in temperature liable to follow an intragluteal injection of 0.05 or 0.1 gm. of salicylate of mercury. In some cases the febrile reaction was not observed until after the second, third or fourth injection; the fever generally lasted for one to three days. He regards it as a sign that further antisiphilitic treatment is needed, but he does not venture to draw any therapeutic conclusions from the absence of a febrile reaction in cases of latent syphilis giving a positive Wassermann reaction.

58. **Prophylaxis of Caisson Disease.**—Bornstein presents evidence to prove that retention of nitrogen is the main cause of the disturbances from caisson work, and that muscular exercise on coming out from the caisson works off this excess of nitrogen more rapidly than any other measure. Even climbing a long flight of steps on coming out is sufficient to throw off the surplus nitrogen. Since the workmen have had to climb nearly 75 feet to the surface in the work on the Elbe tunnel at Hamburg the proportion of workmen affected has dropped from over 3 to less than 0.4 per cent.

62. **Chronic, Febrile, Ulcerative Proctosigmoiditis.**—Strauss gives the autopsy findings in a case in which his diagnosis during life was confirmed post mortem. The process did not extend beyond the upper part of the sigmoid flexure and the pathologic changes were more pronounced downward. He describes further two more cases in which this localized inflammation induced fever but no tumefaction could be palpated and the sigmoid region was not tender. This lack of swelling and tenderness he has noticed in other cases of ulcerative processes in the sigmoid flexure, but the anus is liable to gape. The autopsy findings demonstrate that medical and local measures have little prospect of success in case of such extensive lesions and that operative treatment is necessary. Hermann reported in 1904 24 cured and 11 improved of 50 patients under operative treatment. Strauss advises an artificial anus made in the cecum or the lowest part of the ileum, to leave the inflamed section in peace. Operative treatment is indicated when the general health is suffering and months of local and internal measures have given no permanent relief. Medical measures alone will generally answer the purpose, as he shows by a case in which a young woman had an ulcerative inflammation for 17 cm. above the anus, but was entirely cured by local and general treatment kept up for several months.

66. **Endobronchial Therapy.**—Ephraim has an apparatus for spraying the bronchial ramifications, the flexible instrument being introduced down to the bifurcation, and reports its application in 68 cases of bronchial asthma, the ages ranging from 8 to 71. Only 53 were given the treatment systematically and of these 35 seem to be permanently cured, 6 improved, 5 transiently improved and in 7 no effect was manifest. He uses for the spray a solution of an anesthetic with epinephrin (novocain-suprarenin).

72. **Traumatic Tuberculosis.**—Kappis relates the history of a roofer, about 25 years old, previously strong and apparently healthy, who fell from a height of three stories, a compound fracture of the right thigh resulting. An acute osteomyelitic process developed at the point of the fracture, of tuberculous nature, evidently traceable to an old apical tuberculous process. Amputation became necessary and the much debilitated patient succumbed to the loss of blood although this was only 200 c.c. If the extent of the process had been suspected before the operation the Momburg belt constriction would have been applied. Kappis adds that the family made no claim for damages from the industrial accident but such a claim would certainly have been allowed by the courts in this case.

73. **Enlarged Superficial Lymph Glands with Pulmonary Tuberculosis.**—Zebrowski found enlarged glands on the side of the chest in 186 out of 929 patients with unmistakable tuberculous lesions in the lungs or pleura, that is, in 20 per cent. He also found the enlarged glands in 2.58 per cent. of 1,629 patients without manifest signs of tuberculosis. In 14 in this latter group with enlarged glands the skin and conjunctiva tuberculin tests elicited a positive response, and these tests were not applied in the other 23 patients in this group. Nothing pathologic could be discovered by casual examination in 11 in this group. The enlarged glands were found along the middle axillary line or a little inward from this, along the long thoracic artery. In 12 of the 228 patients presenting these enlarged glands, they could be distinctly traced along the line of the pulsating vessel when looked at from the side, generally at about the fourth interspace and mostly on the right side. In one case the discovery of the enlarged glands first suggested possible tuberculosis of the lungs, and the glands subsided to normal size as the tuberculous process healed under treatment. He discusses the anatomic conditions responsible for involvement of these glands in the pathologic process beyond.

75. **Diagnosis of Duodenal Ulcers.**—Günzburg remarks that the pathologic anatomists still are discovering many duodenal ulcers that had escaped the clinician. In 8 of his total of 18 cases of duodenal ulcer autopsy confirmed his diagnosis; it was based on the pains coming on two or three hours after the meal and relieved by eating, also pains sometimes occurring at 1 or 2 a. m. These attacks of pain may recur through days and months; they are difficult to influence and appear and disappear with periodical regularity. With a history of this kind, duodenal ulcer is almost certain, especially if there is more or less blood in the stools or delay in evacuating a Leube test meal beyond seven hours. The

enlargement of the duodenum is also liable to induce a characteristic tympanitic percussion sound over the quadrate lobe of the liver. This tympanitic zone in the region of the quadrate lobe is caused by the dilated duodenum passing behind this lobe. When the duodenum returns to normal size, as after gastroenterostomy, this resonance is no longer perceived. It appears only when the liver is in its normal place, and when the dullness over the left lobe of the liver can be distinguished from the cardiac dullness. The colon must be emptied before percussing.

76. **Anal or Vulvar Condyloma with Gonorrhea.**—Klingmüller has encountered 8 cases of condylomatous proliferation around the anus or on the perineum of women with a gonorrheal process in the rectum and a case of a granulomatous growth on the prepuce of a male. He ascribes these proliferations to the gonococcus.

77. **Torsion of the Omentum.**—Steiner reports a case of ileus due to torsion of the omentum and compares the clinical picture with 66 similar cases on record. A coexisting hernia is mentioned in nearly every case; this leads to adhesions and the omentum becomes fastened and nodules are liable to develop in it, all favoring torsion. It was readily relieved by laparotomy and resection of the whole of the twisted part of the omentum in his case.

78. **Leukoplakia of the Bladder.**—Herzen reports a case in which he resected a patch of leukoplakia in the bladder, with the involved mucosa and submucosa, after high incision. The patch was 8 or 10 cm. long by 3 to 5 cm. wide; the bleeding surface left was cauterized with the Paquelin and the bladder wall drawn up over it with catgut sutures. The symptoms previously had been dysuria and bacteriuria but no tubercle bacilli had been found. The patient, a man of 24, has been in good health since the operation.

- 88 *The Melanotic Reaction with Cancer. (Klinische Erfahrungen mit der Melostagminreaktion bei bösartigen Geschwülsten.) P. De Agostini.
- 89 Physiologic Action of Radioactive Saline Springs. F. Kriegl.

81. **Diagnosis of Pancreas Disease.**—Glaessner describes the various tests to aid in the diagnosis of pancreatic affections and advises their application. The main point, however, he remarks, is to have the possibility of pancreas trouble occur to one's mind.

82. **Diagnosis of Syphilitic Disturbances in the Upper Air Passages.**—Zange regards the Wassermann reaction as a powerful aid in differentiating suspicious lesions; negative Wassermann findings should impose caution. The lesions themselves are not characteristic, only their mode of development and history. Spirochetes are comparatively rare in tertiary lesions but inoculation of animals with scraps of suspicious tissue will at least exclude tuberculosis. He relates 11 case histories in which the Wassermann reaction gave the clue and led to effectual treatment. In a case with negative Wassermann reaction the findings seemed to be characteristic for gumma or a primary sore on the tonsils but the lesions subsided spontaneously in the course of a few weeks; the retrospective diagnosis was Vincent's angina, and mercurial treatment would have been an error. In another case the bones of the nose were being eaten away and everything except the negative Wassermann reaction indicated syphilis but an operation revealed a chronic osteomyelitic process and a prompt cure followed its evacuation. A mercurial injection for diagnostic purposes has little differential value in the tertiary phase of syphilis, as in many cases the system in this stage seems to be refractory to mercury and iodid.

53. **The Psychopathology of the Tuberculous.**—Liebe relates some of his experiences as director of a tuberculosis sanatorium and states that they could easily be duplicated by other sanatorium physicians, all showing a peculiar egotistic, irritable, spoiled-child attitude of many of the sanatorium patients, entirely contrary to what the same individuals presented in health. He regards these manifestations as part of the disease and states that the complaints and criticisms sometimes made of the institutions, sanatoriums, medical and other attendants, etc., belong also in this category.

58. **The Meiostagmin Reaction with Cancer.**—The experiences with 27 cases of cancer which are reported indicate that Ascoli's meiostagmin reaction may prove an instructive specific means of differentiating malignant disease. The reaction proved positive in all the cancer cases but positive only in 3 out of 27 cases of non-malignant affections.

90. **Duodenal Ulcer.**—This communication from London reports 14 patients with duodenal ulcer cured by operative treatment although one succumbed a month later to pneumonia. Another patient has required two operations since on account of ulcer in the jejunum. In 3 cases there was a concomitant gastric and duodenal ulcer. The operation was done under the diagnosis of cancer in some of the cases but in the others the trouble had been correctly diagnosed from the "hunger pain." This pain is ascribed by zum Busch to the opening of the pylorus when digestion is concluded, the passage of the chyme into the duodenum causing the characteristic pain at this time. In 5 other cases a duodenal ulcer was suspected but no operation was done; 3 of the patients have died, another is still living with much pain, the other has been lost to sight. He does not advocate surgical measures in the early cases but at once when there is recurrence or when the lesion may be regarded as chronic or there are hemorrhages and motor symptoms on the part of the stomach. The gastroenterostomy must always be followed by careful after-treatment, rest and dieting, as the operation alone does not heal the ulcer.

91. **The Hypophysis.**—Kohn reviews what is known to date in regard to the hypophysis and the interrelated ductless glands, remarking that it seems to be certain that the loss of the little parathyroids, not larger than a bean in size, is more serious for the general health than amputation of both legs. Research with extracts of the hypophysis have not given much information to date.

92. **Combined Electric Treatment of Cancer.**—Müller reports 18 cases of cancer in which he has applied a combination of Roentgen rays and high frequency currents with excellent effect.

94. **Local Anesthesia for Minor Operations by the General Practitioner.**—Rothmann recapitulates the details of the Schleich, Braun, Bockenheimer, and other techniques for local anesthesia and urges their more general use in office practice, enumerating the various minor lesions, boils, etc., for which these methods are particularly adapted.

95. **Skin Disease Due to Congestion.**—Strauss has been able to cure previously intractable skin affections by applying treatment based exclusively on relief of congestion in the parts—this cause for the trouble not having been suspected before. In one case a robust man, of 34, a druggist, had

been obliged to change his occupation on account of the severe itching eruption on both legs. It had tormented him for 25 years and had resisted all kinds of treatment, Roentgen rays, etc. Strauss diagnosed the case as a simple lichen maintained by varices in the deep veins, the superficial veins being apparently normal. The patient had applied for a course of Finsen treatment as a last resort, but Strauss dissuaded him from this and applied a compressing bandage after the legs had been elevated for an hour. Under this simple treatment for deep congestion with soothing applications to the superficial lesions, aggravated by scratching, the patient was completely cured in two months. He still wears a compressing bandage on his legs but the tissues feel soft and elastic and except for cicatricial traces there is nothing left of his old trouble.

98. **Anesthetics for Reducing Appetite and Thirst.**—Sternberg thinks that there is a field for the use of substances to dispel hunger in the course of dietetic restrictions as in treatment of gastric ulcer, etc. Cocain reduces hunger and thirst, and this is one of the principal uses for it among the African natives. In treatment of obesity and gastrointestinal ulcers, the abolition of subjective hunger and thirst would aid materially in the cure, and he thinks that this can be accomplished by administration of minute doses of cocain or chloroform water. The anesthetics may also come into play in treatment of dipsomania, bulimia, diabetes, gastrectasia, etc.

- 105 Experiences with Spengler's I. K. M. Gantz.

100. **Tetany in the Elderly.**—Wirth reports three cases of tetany in elderly persons with a chronic stomach or bowel trouble, the tetany being evidently of gastric origin and proving fatal in each case. Dilatation of the stomach preceded the tetany and the latter did not always develop in a complete form. In every case of dilatation of the stomach he advises applying the tests for tetany and, with positive findings, operative treatment without delay. The parathyroid glands may have something to do with the tetany, he suggests, becoming insufficient under the influence of the autointoxication. There is reason to suppose, he adds, that these cases of incomplete tetany are more common than is generally recognized.

104. **Impressions of America.**—In the course of these travel notes Professor von Eiselsberg remarks that the Americans are masters in the art of anesthetization and still cling to ether as it behaves so magically in their hands that there is no ground for seeking to improve on it. He comments on the composure of the American surgeon which nothing apparently can disturb, and the avoidance of speaking during operations, referring to Dr. Brewer's sign language which has been devised for the attendants to avoid speaking. He cites as a curious and interesting fact that in one large office building in Chicago 150 physicians have their offices "without its coming to any differences between them." He adds that none of the surgeons in chief at the hospitals is paid for his services, but on the other hand none has to pay a license fee as in Austria. In his country the hospitals are all built and maintained by the state or community, and he comments with admiring envy on the many privately endowed hospitals in this country and the quarters for pay-patients in the various hospitals, remarking that rooms for pay-patients were included in the plans for reconstruction of the great Vienna city hospital but were afterward abandoned, for one reason, he was told, on account of the objections of the general practitioners. In America, he tells his readers, the practitioners

never objected to this provision for pay-patients, he believes, and there would certainly have been opposition if it had conflicted in any way with any professional interests. The bond between the members of the profession is very close and any infringement of the rights of other members is rigorously punished (*Es ist das Gefühl der Kollegialität ein sehr feines*). Thus the American Medical Association, he continues, has been able with great energy and the best success to attack medical advertisements in the daily papers; one daily paper gets even, however, for the loss of this advertising patronage by printing almost daily communications from the camp of the antivivisectionists. He comments with astonishment on the fact that examination by a state board is required for practice in each separate state and that the right does not extend beyond the borders of the state, saying that when von Pirquet was called from Vienna to Baltimore as professor of pediatrics he had to take the state examination before being allowed to enter on his work. Visits to the leading surgeons are described at length and special points learned from them are emphasized. In conclusion he advises European physicians, and especially surgeons, to take a trip occasionally to America for post-graduate work and inspiration. American surgeons, to say the least, he adds, are abreast with the best in Europe so far as technic is concerned, and the scientific life there is so earnest and so active in the various scientific institutes and it is so stimulated and facilitated by the magnificent endowments, that there can be no doubt that in these institutes also the American colleagues keep pace with the best in Europe. Science and humanity can only benefit by this friendly rivalry between the various nations.

RECENT PROGRESS IN THE SERUM DIAGNOSIS OF SYPHILIS *

HOWARD FOX, M.D.
NEW YORK

In reviewing the literature on the serum diagnosis of syphilis that has appeared since the last meeting of this Association, I have attempted to call attention to the progress that has been made during the year rather than to discuss at length the present status of our knowledge of the subject. The continued interest in the Wassermann reaction, and in various other serodiagnostic tests for syphilis, is shown by the large number of serious researches and clinical reports that have appeared during the past year. Four excellent books on the subject have been published in German, English and French. It was proper that the first of these should have been written by one of the discoverers of the Wassermann reaction, Carl Bruck,¹ whose personal experience with the test has been enormous. He has given a most excellent presentation of the whole subject from both the theoretical and practical standpoints. Noguchi² has also written a book of great value, in which special attention is devoted to his own modification. Interesting booklets have also been published by Gastou and Girault³ in France, and by Mulzer⁴ in Germany.

VARIOUS SERODIAGNOSTIC TESTS

Before discussing the more important subject of the Wassermann reaction I should like to call attention to some of the serodiagnostic tests for syphilis, depending on principles other than those of complement-fixation. I had supposed that the status of the various precipitation tests for syphilis was fairly well settled at the last meeting of this association. In a paper read on that occasion Wieder and L'Engle,⁵ from experiments with sodium taurocholate and glycocholate, lecithin, taurin and water, concluded that the proportion of positive results in non-syphilitics was too high to make the test of value. This seemed to be the prevailing opinion last year and is, I think, at present, in spite of two recent reports on the subject. Rosenfeld and Tannhauser,⁶ in

a series of 131 cases, obtained results that compared favorably with those of the Wassermann test. Tanton and Combe,⁷ from an examination of sixteen cases, concluded that the precipitation method was equally specific, in addition to being much simpler than the Wassermann reaction. Sourd and Pagniez,⁸ however, found that the precipitation test gave six positive reactions in non-syphilitic cases, and Paris and Sabaréanu,⁹ from an examination of fifty-three cases, conclude that the test is of no diagnostic value whatever. A similar opinion is expressed by Laub and Novotny¹⁰ in regard to the value of the reaction for pathologic-anatomic diagnosis, their experiments including a simultaneous test of ninety-eight cadaver serums. Unfavorable results are also reported by Minelli and Gavazzoni.¹¹ In all of the above communications the test with glycocholate of soda was the one employed.

Since the publication of Noguchi and Moore¹² last July on the butyric acid test in the metasymphilitic and nervous diseases, nothing further has been written on this method. In their experiments the writers found that the test was not absolutely specific, positive reactions having been obtained in two out of thirty-seven psychoses not in any way related to syphilis. In his book on serum diagnosis Noguchi states that the butyric acid test while not entirely specific, is at times more valuable than the Wassermann reaction in excluding syphilis, for instance, when the reaction is negative.

Assuming that the *modus operandi* of the Wassermann reaction depends on a precipitation, Jacobsthal¹³ suggests a method which he terms the "optic serodiagnosis of syphilis." The patient's serum is mixed with alcoholic extract of syphilitic liver in the proportion of 1 to 10 and the resulting precipitate is examined with the dark-field illuminator. A strong positive reaction appears as a clumpy precipitate, a weak positive reaction as a small conglomeration of little fat particles, while a negative is shown as a thick emulsion of very fine dancing fat particles. In comparing his method with the Wassermann reaction Jacobsthal claims that, after having acquired the necessary experience, his results with the two tests were identical.

It can hardly be of more than historical interest to discuss the color reaction suggested by Schürmann,¹⁴ that has been so thoroughly discredited by subsequent experimentation. Indeed, it seems strange that so much has been written on the subject when it seemed almost from the start that the method was valueless. A few words about this proposed method may aid in preventing others from further experimentation. Schürmann thought that there might possibly be some substance in the blood of syphilitics whose presence could be recognized by a color reaction. It occurred to him that lactic acid might play a part in the reaction, as this substance had been present in one of his most reliable extracts. His first experience with Uffelmann's reagent being unsuccessful, he was led to use perhydrol in combination with phenol and chlorid of iron. According to Schürmann, when the reagents were mixed with normal serum a light green color appeared at the upper portion of the mixture. This either disappeared or changed to a light green tint on shaking, the solution remaining clear. When syphilitic serum was used a blackish-brown dull tint appeared almost immediately, the solution giving the impression of a thick mixture.

Employing his method in eighty-four cases simultaneously with the Wassermann test, Schürmann claimed to have obtained identical results. In a comparison of the Schürmann with the Wassermann test in 154 cases of undoubted syphilis Meirowsky¹⁵ obtained 62.3 per cent. of positive reactions for the Wassermann test as opposed to 14.9 per cent. for the Schürmann method. The list of investigators whose results have been unfavorable, and who conclude that the test is of no clinical value, includes Biach,¹⁶ Bonola,¹⁷ Braunstein,¹⁸ Bruck,¹ Galambos,¹⁹ Roth and Goldner,²⁰ Schminke and Stoeber,²¹ C. Stern,²² Stühmer,²³ Symanski, Hirschbruch and Gardiewski.²⁴ According to the chemical examination of Braunstein,¹⁸ the reaction is a process of oxidation, the perhydrol oxidizing the phenol by means of the iron chlorid.

Interesting results have been obtained by Nicolas, Favre and Gautier²⁵ with dermic and intradermic reactions in syphilis, analogous to the reaction caused by tuberculin for the diagnosis of tuberculosis. For this purpose the experimenters used a concentrated glycerinated extract of liver of syphilitic fetus which they termed "syphiline." When this extract was used by the dermic method (as in the von Pirquet test), no change was noted. When, however, the extract was injected intradermically a reaction consisting of redness and nodular infiltration was obtained in a large proportion of

the twelve cases examined. In a second contribution the same authors²⁶ give the results in fifty cases, of a comparison of their test with the Wassermann reaction. The results were in agreement in forty-two cases. Of the remaining eight cases five seemed to favor the correctness of the diagnosis by the intradermic test, while one favored the Wassermann method.

The relation of the Wassermann test to the antitryptic power of the blood in syphilis was studied by Fuerstenberg and Trebing.²⁷ The determination of the antitryptic index (using a modified method of Müller and Jochman) was made simultaneously with the Wassermann method in sixty-one cases of syphilis and other diseases. It was found that in cases of undoubted syphilis giving a positive reaction the antitryptic titer or index was never increased. In the majority of cases it was diminished. Whether this test will prove of value, from the fact that an increased antitryptic titer would seem to exclude syphilis, can be judged only after further investigation with this method.

According to Achard, Benard and Gagneux,²⁸ the so-called leukodiagnosis, which is based on specific sensitiveness of leukocytes *in vitro* to certain normal or pathologic products, may also be applied to syphilis. The specific principle used by these writers was a glycerinated extract of spleen of a congenitally syphilitic infant containing *Spirochaeta pallida*. The strongest influence on the leukocytes was obtained with a 5 per cent. dilution of the extract. In this strength the leukocytic activity was found to be more or less increased in syphilis, while it was not at all influenced in healthy subjects. It was found in their investigations that the strongest reactions correspond to the period of early secondary syphilis, while the reactions were weaker in hereditary manifestations of the disease and in tabes and paresis.

The reaction first described by Much and Holzmann was tried by Hamburger²⁹ in twenty-two cases of syphilis simultaneously with the Wassermann test. The results obtained were entirely contradictory, the writer concluding that the test has no value in syphilis. The reaction which has previously been seen only in certain insane persons, especially dementia præcox, consists in an inhibitory action to the hemolysing power of cobra venom.

In experimenting with various hemolysing agents in different diseases it was found by Richard Weil³⁰ that the erythrocytes of syphilitics were especially resistant to the hemolysing power of cobra venom. This fact has been utilized as the basis of a diagnostic test for syphilis that promises to be of considerable value. The technic of the procedure is as follows: Blood is drawn into a 2 per cent. solution of sodium citrate, washed and made into a 4 per cent. suspension in normal salt solution. It is then tested on the following day. Equal amounts of venom at 1 to 800 and 1 to 1,500 are added and after one hour of incubation the results are read. It has been

found that syphilitic cells resist a solution of 1 to 1,800; that is, twice as strong as that which destroys the control. The reaction was found to be marked in 90 per cent. of the cases of syphilis, the percentage of positive reactions being smaller in tabes than in paresis. In several non-syphilitic affections in which the Wassermann test was positive (three cases of scarlatina, two cases of polycythemia and one case of scleroderma) the Weil test showed a negative reaction. Some advantages which Weil claims for his test are that it can be used in cases of jaundice. It is positive for some time after mercurial treatment has abolished the Wassermann reaction. It is finally positive in a very large percentage of old quiescent cases in which the Wassermann test is negative. Dr. Weil informs me in a personal communication that he considers his test too delicate for general use, as a very considerable amount of practice is required in order to interpret the results obtained.

The meiotagmin reaction suggested by Ascoli and used by him as a diagnostic procedure in typhoid fever has been applied by Izar³¹ to syphilis. The test is a physico-chemical reaction of immunity depending on a change in surface tension of the fluids employed. When the serum of a syphilitic is mixed with its corresponding antigen and placed in the thermostat for two hours there is a diminution in surface tension as shown by an increase in the number of drops of a measured amount of the fluids. According to Izar the test was found to be entirely specific. A positive reaction was obtained in twelve cases of syphilis, while all of the non-syphilitic cases gave negative results, including two cases of leprosy in which the Wassermann reaction had been positive.

WASSERMANN TEST AND ITS MODIFICATIONS

In reviewing the recent progress of the Wassermann reaction I should first like to discuss some of the more important and practical contributions that relate to the technic of the method. A simple means of obtaining the patient's blood for examination has been suggested by Muck.³² The superficial veins of the neck are compressed by Bier's method and the mucous membrane of the anterior portion of the septum is scratched with a small needle or knife. In about three minutes as much as 20 c.c. of blood can be readily secured. The bleeding stops on removal of the compression, or on introduction of a pledget of cotton into the nose. Another method of obtaining blood where a venepuncture is difficult or not desirable, as in infants, is suggested by Somani.³³ After scarifying the skin he applies a cupping apparatus with an outlet below attached to a test-tube to receive the blood, and a suction-pump attached in the center. To this and other cupping methods Mulzer makes the objection that the apparatus is difficult to sterilize and that unsightly scars are left which if the method were widely adopted and known to the laity might at times prove compromising.

Finkelstein³⁴ has devised an apparatus for determining quantitatively the strength of a positive reaction. He uses a glass funnel (of a shape to fit a centrifuge), at the bottom of which a graduated tube is fused. The

undissolved corpuscles of the case to be examined and of the known positive cases are poured into two separate funnels, which are then centrifugalized and the result mathematically read. A somewhat similar apparatus has been recently suggested by Heimann.³⁵

As yet no one has produced the much-desired artificial antigen which shall prove as reliable and specific as the various organ extracts now in use. The artificial antigen of Sachs and Rondoni has, however, been found in the hands of Eisenberg and Nitsch³⁶ to be the equal of organ extracts, while unfavorable results in its use were obtained by Isabolinsky.³⁷ An artificial antigen has been suggested by Schürmann³⁸ which, in addition to lecithin, contains glycerophosphate of sodium and ammonium vanadate. This has been tested by Rajchman and Zygmunt³⁹ with disappointing results. They conclude that artificially prepared antigens are not reliable substitutes for alcoholic organ extracts, as in weak doses they often fail to give positive reactions with syphilitic serums and in stronger doses give a positive reaction with normal serums.

It was recently pointed out by Wechselmann⁴⁰ that the failure to obtain higher percentages by positive reactions in cases of undoubted syphilis might be due to interference from the presence of complementoids. By removing these disturbing bodies, by shaking the serum with barium sulphate, better results were obtained than with the regular Wassermann method. This procedure has been tried by Lange⁴¹ with strikingly good results in a series of 800 cases, in which both methods were simultaneously performed. In 551 syphilitic serums the Wechselmann test yielded 85 per cent. of positive reactions, as against 77 per cent. for the Wassermann method. In non-syphilitic control cases the Wechselmann test gave only negative reactions. Shaking the serum with barium sulphate not only adds to the delicacy of the test, but also destroys the complement, making it unnecessary to inactivate the patient's serum by heating to 56 C. for a half hour. Lange, therefore, at the present time uses the barium sulphate treatment of the serum as a substitute for inactivation by heat.

In order that positive and negative control serums may always be at hand Hecht⁴² recommended that they be preserved by means of drying. Small amounts, such as 0.5 c.c., are dried in watch crystals. When the serum is needed it is dissolved in an equal amount of salt solution, after which equal amounts of distilled water are added. The combination of salt solution and water is advised, as when distilled water is added to the dried serum certain substances (possibly globulins) remain undissolved and float about in the mixture as cloudy masses.

According to Blanck and Friedmann⁴³ alcoholic extracts of syphilitic liver at times lose their usefulness for the Wassermann reaction by being kept in the ice-chest or in a cold solution. They found that in some cases this could be remedied by allowing the extract to remain in a thermostat for several days. To preserve their efficiency best it is advised to keep extracts in a warm room.

Further researches on the feasibility of using urine in place of serum for the Wassermann reaction have been made by Pollio.⁴⁴ His conclusions are similar to those of Höhne, that the use of the urine has no practical value, as too large a percentage of positive reactions are given in non-syphilitic cases. Even Blumenthal and Wile, who first experimented with urine, admitted that it was not quite as reliable as blood-serum for the Wassermann test. Bauer and Hirsch⁴⁵ conclude that in positive reactions obtained by using urine the inhibition of hemolysis is due to the globulin fraction of the urine. They obtained negative results in non-syphilitic urine containing albumin and in syphilitic urine containing no albumin, or albumin in small amounts.

In a discussion by Stern⁴⁶ of uncertain and paradoxical reactions that are so often obtained by every serologist, some of the rules are given that are at present followed in the laboratory of the Neisser clinic at Breslau. Every serum is tested both by the original Wassermann and by the Stern method; that is, in both active and inactive condition. When the results are not in accord the serums of the cases that are clinically doubtful are tested once or more times, using various extracts known to be reliable. The same procedure is followed in serums giving a partial inhibition of hemolysis and in serums of apparently healthy persons giving a positive reaction.

That the Wassermann reaction as originally performed is not absolutely satisfactory from either the theoretical or practical standpoint is apparent from the many attempts that have been made to improve and simplify the test. Of the different methods depending on the principle of complement-fixation there are eight which might be termed systems, which were published before June, 1909. The principles on which these different systems are constructed are very plainly shown in a comparative table by Noguchi in his book on serum diagnosis.

Since last June another "system" has been added to the list by Foix,⁴⁷ who suggests the use of rabbit's blood for the indicator in place of sheep's blood. During the past year the modifications⁴⁸ of Bauer, Tschernogubow (second method), and more especially those of Hecht and Stern, have been the subject of a good deal of

investigation in Europe, while the method of Noguchi has received especial attention in America. The final word is yet to be pronounced on these various modifications, as there is not yet an absolute opinion as to their value.

Very favorable results with the Hecht test are reported by König,⁴⁹ who finds it superior to both the original method and that of Margarete Stern. In a more recent communication on the method of Hecht, the same writer⁵⁰ concludes that it fulfils all the requirements of any modification, which are that: 1. It must have a scientific basis. 2. It must be simpler and more delicate than the original method. 3. It should never give erroneous results. Demanche and Ménard⁵¹ conclude that the results of the Hecht test are practically as reliable as those of the original method. Scholtz⁵² speaks of the test as simple and reliable. From his experience with 500 cases performed simultaneously with the Wassermann test, Werther⁵³ considers the Hecht method preferable, as it gives less often an incomplete inhibition; e. g., doubtful results. Favorable expressions of opinion on this method are also given by Stanculéanu and Liebreich⁵⁴ and by Sabrazes and Eckenstein.⁵⁵ Unsatisfactory results with the Hecht and with the Bauer test are reported by Hügel and Reute,⁵⁶ while both of these methods, as well as those of Stern and Tschernogubow, are condemned by Isabolinsky as giving less certain results than the Wassermann test.

The modification of the Hecht test, still further simplified by Fleming by the use of very small amounts of the ingredients, is condemned on the one hand by Bassett-Smith⁵⁷ and recommended on the other hand by Clemenger.⁵⁸ The former found that hemolysis failed to occur in 30 per cent. of his cases, whereas the latter found only 5 per cent. of failures.

Opinion on the second method proposed by Tschernogubow (the first method having been abandoned) do not seem to entirely agree. Stühmer,⁵⁹ from a comparative examination with the Wassermann test in over 300 cases, concludes that the procedure of Tschernogubow represents a great simplification and that its results are at least as reliable as those given by the original method. On the other hand, Guth⁶⁰ considers the test unsuited for a large laboratory, as the serum must be used immediately after being obtained, while for practicing physicians its performance is difficult.

48. The modification of Bauer dispenses with immune (artificial) amboceptor and depends on the natural antishoop amboceptor present in the patient's serum. The Hecht method dispenses not only with the immune amboceptor but also with the guinea-pig complement, utilizing the complement normally present in the patient's serum. Stern in her modification also relies on human complement, but unlike Hecht uses the immune amboceptor. Tschernogubow in his second method employs the red corpuscles of the guinea-pig instead of the sheep as his indicator. He also makes use of human complement. Noguchi employs human corpuscles as the indicator, guinea-pig serum for complement, and antihuman amboceptor.

In reviewing the results obtained with the Stern modification we again find conflicting reports. An unfavorable opinion is given by Kleinschmidt,⁶¹ who thinks that the use of this procedure may lead to errors in diagnosis. In a comparative examination of 200 cases discrepancies were found to the advantage of the Wassermann method in twenty-five cases. In 5 per cent. of the cases there was not sufficient complement to complete the hemolysis. Jacobsen and Bachmann⁶² consider the modification of Bauer and Stern unreliable, as they give too many positive reactions in non-syphilitic cases. As treated cases of syphilis generally show an increased amount of amboceptor and complement, they suggest that a positive Bauer reaction (depending on natural amboceptor) or a positive Stern (depending on natural complement) might be considered as giving an unfavorable prognosis and indicating prolonged treatment. Schlimpert⁶³ and Meirowsky⁶⁴ warmly recommend the Stern modification, though both of these writers urge that it be performed simultaneously with the original Wassermann method.

NOGUCHI TEST

From this cursory review of the modifications that have been tested with considerable thoroughness abroad it is easy to see that no one method has succeeded in replacing the original procedure of Wassermann. It is unfortunate that the system of Noguchi has not as yet been more seriously considered by our foreign colleagues. In the recent book on serum diagnosis by Gastou and Giraud⁶⁵ the method is described at some length, although it has been practically performed only in a few cases. Among those of us in America who have had experience with the Noguchi method there is little doubt as to its very great value. The principles of the test, as well as minute instructions for preparing the reagents, are so plainly described in Noguchi's book that it seems strange that the method has not at least been given a trial in some of the foreign laboratories. In a recent contribution Noguchi⁶⁶ has tabulated the work of different American investigators who have experimented with his method, and it may be said that the results speak for themselves. The test has now been tried in over 8,500 cases, many of these in comparison with the regular Wassermann test. Kaplan, who formerly reported 8 per cent. positive reactions in non-syphilitic cases, states that during the past five months no such non-specific reactions have occurred. To meet the objections of Swift, who found thirty-five positive reactions in 201 non-syphilitic cases, Noguchi recently gave a public demonstration of his test at the clinic of the Pennsylvania Hospital. The serums of fifty-nine patients were simultaneously examined by Dr. Noguchi with his method, and by Dr. Swift, using the original technic of Wassermann. The results were absolutely identical.

SPECIFICITY OF WASSERMANN REACTION

The question of the specificity of the Wassermann reaction finally appears to be nearing a solution. The

list of non-syphilitic diseases in which a positive reaction can be obtained more or less often is becoming more definitely settled. To this list, which includes leprosy, frambesia, sleeping-sickness, scarlatina, and malaria, must now be added, apparently, lupus erythematosus acutus. Fortunately these conditions do not often present any difficulty in being clinically differentiated from syphilis.

Several communications on the Wassermann reaction in leprosy have recently appeared in which the number of patients examined was fairly large. While agreeing that leprosy in general often gives a positive reaction, they do not agree as to the type of the disease in which the reaction is found. Thus Ehlers and Bourret,⁶⁶ in forty-seven cases of nodular and anesthetic types, found positive reactions in all except two cases. On the other hand, Eliasberg,⁶⁷ in fifty cases, found a much higher proportion of positive reactions in the nodular than in the anesthetic type. My own results⁶⁸ in an examination of sixty patients agree closely with those of Eliasberg, the latter obtaining only three reactions in nineteen anesthetic cases, while I found three reactions in twenty-two cases of this type.

Teissier and Bénard⁶⁹ in 100 cases of scarlatina found the reaction partially or completely positive in 84 per cent. of the cases. The reaction appeared at times as early as the third day and invariably disappeared at the end of convalescence. Using extract of human heart as antigen, Nanu-Muscel and Titu⁷⁰ obtained only negative reactions in 12 cases of malaria. In 8 cases the examination was made at the height of the paroxysm when the blood showed the presence of the plasmodium. According to Boehm⁷¹ a positive reaction can be obtained in malaria only when the parasites are present in the blood.

In a case of that very rare condition, lupus erythematosus acutus, Reinhart⁷² obtained a positive Wassermann reaction on two different occasions. After the patient's death a positive reaction was obtained from the blood. The autopsy showed no evidence whatever of syphilis. A second case of this disease is reported by Hauck⁷³ in which on two occasions a positive reaction was found. In this case the patient survived and failed to show the reaction after the acute symptoms had subsided.

Interesting results are recorded by Wolfsohn⁷⁴ from an examination of 50 patients shortly after ether narcosis. A more or less strong positive reaction was found in 13 cases. Two of these patients were syphilitics, in whom the positive reaction persisted, while in the other cases the reaction disappeared in a few days. Wolfsohn concludes that in 22 per cent. of the cases a temporary positive reaction may be present as a result of ether narcosis. He considers his results

such findings might be explained on theoretical grounds in three ways. In the first place, the mothers might have been victims of latent syphilis. In the second place, the mothers might have been healthy, the positive reaction being due to inhibitory substances that had been produced in the child and passed through the dividing wall of the placenta into the mother's circulation. In the third place, the mothers might have been immune to syphilis, assuming that the inhibitory substances represent immune bodies produced in either fetal or maternal organism and circulating in the mother's blood. To settle the question Baisch combined the serologic examination of the mother and child with examinations for the *Spirochæta pallida* in the placenta. He found in these clinically healthy women, giving a positive Wassermann reaction, that the spirochetes could be found in both fetal and maternal portions of the placenta as well as in the maternal circulation, apparently proving the first possibility, namely, that the mothers were the bearers of latent syphilis.

Speaking further for this explanation and against the possibility of the reaction being due to inhibitory bodies passing from the child to the mother, is the fact that the positive reaction in the mother does not disappear after the birth of the child. Furthermore, the reaction can be positive in the mother and negative in the child. Bruck has pointed out that a number of cases have been reported in which a syphilitic child gave a negative reaction at birth, and later when manifestations appeared the reaction became positive. In spite of this the mother at the time of the birth gave a positive reaction. In these cases a passage of the inhibitory bodies from child to mother was certainly impossible. The most difficult cases to explain would be the ones in which the mothers, in addition to being clinically healthy, gave a negative reaction while their offspring were shown to be undoubtedly syphilitic from demonstration of the presence of the spirochetes. It might be thought that in these cases we had to deal with pure paternal heredity, or the explanation might be found in the failure of the Wassermann test to show a positive reaction. The proof that the explanation lay in the failure of the test was apparent from the fact that in the negative as in the positively reacting mothers, spirochetes were found in both portions of the placenta and in the maternal circulation.

Not only may our ideas concerning Colles' law have to be revised, but also those concerning the law of Profeta, which says that apparently healthy children of syphilitic parents are immune to syphilis, at least up to the time of puberty. The presence of a positive Wassermann reaction in a large number of these supposedly healthy children goes far to prove that here again the immunity to syphilis is only apparent.

That not only hereditarily syphilitic infants but also older children suffering from hereditary syphilis give a higher proportion of positive reactions has been shown by Bertin and Gayet.⁹⁴ In examining 25 undoubted cases of hereditary syphilis they found positive reactions in all but one case. Knoepfelmacher and Lehn-dorff⁹⁵ also conclude that older heredo-syphilitic children give a positive Wassermann reaction more often than adults in the late stage of acquired syphilis.

In conclusion it would seem that there has been some very substantial progress during the past year in the

serum diagnosis of syphilis. The continued investigations on the Wassermann test have not only added much that is new to our knowledge, but have tended to confirm the view that the reaction is one of very great practical value. The results obtained in a number of other diagnostic tests for syphilis must at least be considered as encouraging.

SUMMARY

1. The various precipitation tests for the diagnosis of syphilis are too unreliable to be of much practical value.

2. The Schürmann color reaction has been extensively tried and found to be worthless.

3. The favorable results that have been claimed for the intradermic reaction are at least encouraging, as the performance of the test seems to be simple.

4. Excellent results have been claimed by Richard Weil for his cobra venom test. They are, however, somewhat lessened in value by the fact that very considerable experience is required to perform the reaction.

5. Further investigations are required to show whether the leuko-diagnosis, the antitryptic index or the meio-stagmin reaction can be used as diagnostic aids in syphilis. The results obtained with the Much-Holzmann reaction appear to be of no value.

6. The artificial antigens of Sachs and Rondoni, and of Schürmann for the Wassermann reaction have not succeeded in replacing the use of organ extracts.

7. The use of barium sulphate suggested by Wechselmann to remove the disturbing complementoids from the patient's serum has apparently given a greater proportion of positive reactions than those obtained by the original Wassermann method.

8. The use of urine in place of serum for the Wassermann reaction is not to be recommended.

9. No single modification has as yet entirely replaced the original Wassermann method. The modifications of Hecht and of Stern have apparently given good results abroad, while the Noguchi test has received almost universal recognition in America. The methods of Bauer and of Tschernogubow (second test) appear to be of much less value.

10. To the list of non-syphilitic diseases which at times give a positive Wassermann reaction, must apparently be added lupus erythematosus acutus. It has also been found that many cases give a positive reaction following ether narcosis.

11. The diagnostic value of a positive reaction is generally recognized. There is no general agreement as yet regarding the value of the test as a guide for treatment.

12. From recent serologic investigations it would appear that syphilis plays a very important rôle in the etiology of aortic insufficiency. Syphilis is probably of more importance in the causation of nerve-deafness than has been previously supposed. There is apparently little or no relation between syphilis and ozena.

13. A new field seems to have been opened by the Wassermann reaction for the discussion of the problem of the inheritance of syphilis and of the interpretation of the laws of Colles and Profeta.

14. In the field of pathologic-anatomic diagnosis the Wassermann reaction seems to be of considerable value.

15. Serologic examinations have shown that the percentage of syphilitic infections in prostitutes is extremely high.

Marine-Hospital Service

WASHINGTON, D. C.

While engaged in the study of 130 cases of amebiasis (amebic dysentery) during portions of 1907, 1908 and 1909, at the Marine Hospital in San Francisco, it was noted that the majority of the patients showed symptoms of secondary complications. Some complained of rheumatic pains and neuralgias; others complained of headache and indigestion and became constipated at times; others showed lesions on the hands, feet and legs which were thought to be trophic in character and which were usually in the form of dryness of the skin, or in the form of small pinhead-sized vesicles, which tended to coalesce and later to form bullæ. There was also more or less marked interference with the mobility of the various joints and of the spine.

In searching for the cause of these symptoms the x-ray demonstrated that the rheumatic pains, neuralgias, etc., were apparently caused by the presence of some sort of deposit on the articular surfaces of the vertebræ, which so encroached on the foramina giving exit to the nerves, particularly at the posterior portion, as to produce mechanical pressure on the nerves at their exit. The headache, constipation and indigestion seemed to be due to injury to the intestinal mucous membrane by the amebas. Microscopic examination of the feces constantly showed muscle-fibers, starch, vegetable cells and fibers, ammonium and magnesium phosphate crystals, fatty acid crystals, oxalate of calcium crystals, cholesterol plates, mucus, pus, blood, blood pigment, soaps and fats, amebas, monads and frequently eggs of other parasites, as hookworm, roundworm, whipworm and, at times, the hyphæ and sporangia of molds. The trophic lesions were thought to be due to the mechanical pressure on the nerves, which had been so long continued as to interfere with their functions; the loss of motion in the spine and the joints to the pressure of the deposits, above mentioned, which could be seen in the x-ray plates. On examining my first pellagra patient, last November in Columbia, I was much struck by the resemblance pellagra had to the cases of amebiasis above mentioned. After reading all the literature on pellagra that I could, and from talking with Lavinder and others who had had experience with pellagra, the following working hypothesis was formulated, and the studies carried out in Columbia, S. C., were directed toward proving or disproving the various parts of the hypothesis.

WORKING HYPOTHESIS REGARDING THE NATURE OF THE DISEASE

The hypothesis is as follows: Pellagra is a disease resulting from an injury to the intestinal mucous membrane, produced by the ameba. As a result of the ulceration there is an inflammatory process extending throughout the alimentary tract which interferes with the absorptive power of the intestine and the manufacture of the digestive ferments normally produced in the intestines. Later, owing to long-continued inflammation in the intestine, the pancreas and liver undergo inflammatory change which interferes with the quality and quantity of the digestive juices that they produce, with the result that the food ingested is improperly

digested. The presence in the intestine of undigested food favors fermentation and putrefaction of its elements, with the production of certain toxins, ptomains and intermediate products of digestion which are harmful to the body.

As it has been shown by Herter that the *Bacillus aerogenes capsulatus* is present in the intestines of carnivora, and readily ferments proteid matter, it was decided to look for it as one of the possible causes of the fermentation. The fermentation of the carbohydrates could be accounted for by the colon bacillus.

The insanity of pellagra was assumed to be due to the severe and long-continued toxemia. The lesions on the hands, neck, feet, face and genitalia were assumed to be due to two factors: first, the mechanical pressure on the nerves at their exit from the spinal canal, and second, the degeneration of the nerves themselves as a result of the toxemia. The degeneration of the cord was assumed to be due to the long-continued mechanical pressure on the posterior roots of the spinal nerves, which would tend to have the same effect as section of the nerve.

It was assumed that the seasonal recurrence of the disease was due to the extremes of atmospheric temperature which exist during the so-called pellagra season, namely, March, April and May, and September, October and November. This assumption was not formulated until I had been in Columbia some time and had noted the changes myself.

INVESTIGATION OF HYPOTHESIS

An outline of the work done along the above lines will now be given: Examination of the stools of fifty-two of the patients showed amebas constantly present in the stools of fifty. In the two cases in which amebas were not found the stools were not satisfactory, in that they were not sufficiently liquid, and other specimens could not be obtained. Ulceration and damage to the intestine was shown, in all stools examined, by the presence of mucus, pus, blood pigment and blood.

That the liver and pancreas were damaged was shown at autopsy by the fact that both of these organs revealed cirrhotic changes, the pancreas especially being so hard as to be almost leathery in consistence; this was also evidenced by the presence of muscle fibers, vegetable cells and fibers, starch, soaps and fats in the stools. The latter observation, in addition to the fact that a damaged and ulcerated intestine cannot absorb as well as a normal one, might also be accepted as partial evidence as to faulty absorptive power on the part of the intestine.

Fermentation and putrefaction were shown by the presence of crystals in quantity in the stools, by the odor, by the fact that the stools were frequently fermenting and giving off bubbles of gas in the paper cups in which they were brought to the laboratory. The stools were invariably acid in reaction, frequently requiring as much as 5 to 10 c.c. of a 1/10 normal solution of sodium hydroxid to produce a reaction with phenolphthalein in 25 to 30 c.c. of stool. Van Noorden states in effect, in his work on "Metabolism and Nutrition," that acid fermentations, in that they withdraw bases from the blood to form compounds with the acids produced, diminish the alkalinity of the blood, and produce serious results.

The *Bacillus aerogenes capsulatus* was found in one case, according to the method of Welch, by injecting fecal matter into the ear vein of a rabbit, after a few minutes killing the rabbit, and allowing it to remain on the top of the incubator till the following day, when it

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

was seen that the body was swollen with an inflammable gas, the organs were much decomposed, and the tissues generally were edematous.

In one case which had been under treatment until the stool was neutral in reaction, and in which crystals and the other signs of fermentation and putrefaction could not be found, the *Bacillus aerogenes capsulatus* could not be recovered. On account of the limited time and the difficulty of obtaining animals more experiments of this kind could not be made.

As regards the cause of the insanity, nothing definite was worked out, but it was noted that sudden changes in the atmospheric temperature made the cases much more toxic, and whereas the patients may have been fairly sane, they would become excited and would frequently have to be placed under restraint. This applied not only to the pellagrins, but to other patients in the asylum as well. This I cannot satisfactorily explain, unless it be due to the alternating warming and chilling of the surface of the body, causing the blood to leave the surface capillaries and producing an engorgement of the vessels of the intestines, and by so doing increasing the activity of the processes at work therein.

As to the lesions on various parts of the body, in every case of pellagra in which radiographs were made the plates showed deposits in the spinal foramina which apparently produced pressure on the nerves. As to the part played by toxic degeneration of the nerves themselves, I can only repeat what I was told by Dr. Achucaro of the Government Hospital for the Insane, Washington, D. C., that experiments show that when various tissues, such as nerve, muscle and fat, are allowed to decompose, the nerve, being the most highly specialized of all the tissues, shows evidences of degeneration first.

It is possible that several factors may be concerned in the seasonal recurrence of the disease: First, renewed activity and new infections with amebas in the spring of the year; second, engorgement of the intestines due to chilling of the body surface; third, the growth of molds in food products, with resulting changes in these products, which could favor fermentation in a person already debilitated.

As to the degeneration of the posterolateral columns of the spinal cord, Marie made the observation that the degeneration began in the posterior roots of the spinal nerves; the radiographs show that the pressure does come on the posterior roots of these nerves, at about the site of the ganglion. Further, at the only autopsy I could obtain, it was noticed that the foramina were so filled with what seemed to be a firm cartilage-like deposit that the nerves were wedged therein, and a large-sized sewing-needle or a Japanese toothpick could not be pushed through the foramina. The spinal canal was also partially filled.

In Gray's "Anatomy" the following statements are made:

The roots of the cervical nerves increase in size from the first to the fifth and then remain the same size to the eighth. The posterior bear a proportion to the anterior as 3 to 1, which is much greater than in any other region.

It may be seen from the skeleton and the radiographs that the foramina in the cervical region decrease in size from above downwards, whereas as above stated, the nerves increase. These facts would seem to account for the lesions on the hands (fifth, sixth, seventh, eighth cervical and first dorsal), face and neck (third and fourth cervical).

With reference to the dorsal nerves Gray says, "The roots of the dorsal nerves are of small size, and vary but slightly from the second to the last." Examination of the skeleton shows these foramina to be larger than the lower cervical, and therefore there are no lesions on the parts innervated by the dorsal nerves.

The lesions on the legs and feet are due to pressure on the first and second sacral nerves, of which Gray says, "The roots of the upper sacral nerves are the largest of all the spinal nerves; while those of the lowest sacral and coccygeal nerves are the smallest." The foramina are larger than the other intervertebral foramina but are more tortuous, and as the spinal canal in the sacrum is incomplete posteriorly and flattened, it is possible that any deposit here will produce pressure symptoms as in the other vertebrae.

TREATMENT

The amebiasis was treated by enemas of quinin bisulphate in normal salt solution. After a preliminary purge, the patient was put on a diet of milk, toast, rice and starchy foods. To aid the pancreas, pancreatin was administered in capsules coated with phenylsalicylate, in order that the hydrochloric acid of the stomach could not act on and destroy the pancreatin. To assist the pancreatin and neutralize the acidity present in the intestine, sodium bicarbonate was given, also in capsules coated with phenylsalicylate. To prevent accumulations of food and resulting fermentations, small doses of salts were given often enough to cause one or two bowel movements per day, not counting the results of the enema as a movement. The deposits were treated by inunctions of mercury and the internal administration of iodid of potassium, both pushed to the therapeutic limit. Rest in bed was ordered till the acute symptoms had subsided.

In all, twenty-five patients were treated, with the following results: Three died; of these, two died of chronic amebic dysentery, the pellagra lesions having practically disappeared; the other, just prior to death, was having from eighteen to twenty stools per day, and the pellagra lesions had improved, until the week before death, when secondary infections began in the lesions, and they became purulent. Twelve patients improved in varying degrees, both mentally and physically. Since these were insane negroes and no cooperation could be received from the patients themselves, it was surprising that they improved at all. Six others also were improved, the last time I saw them, and, in accordance with information just received, they are continuing to improve. Four recovered, and all symptoms of pellagra had disappeared, except a slight increase in the patellar reflexes.

While many of the studies seem more or less suggestive, and while the percentage of improved and recovered seems encouraging, I feel that, in accordance with accepted medical standards, no conclusions can be drawn as yet, and that much longer and more detailed studies will be needed to prove or disprove the value of the researches just outlined.

In conclusion, I wish to acknowledge my indebtedness to Dr. J. W. Babcock, of the State Asylum at Columbia, for his kindnesses, assistance and many courtesies. I also wish to thank Dr. R. W. Gibbes, of Columbia, for the excellent radiographs he has taken, and the members of the asylum staff and the physicians of Columbia for permission to study their cases.

Since completing my studies in Columbia, I have seen nine positive and sixteen suspicious cases in the Philadelphia Hospital for the Insane. Of twelve specimens of stools examined from these cases, all showed amebas.

THE FARM; THE NEXT POINT OF ATTACK IN SANITARY PROGRESS *

ALLEN W. FREEMAN, M.D.

Assistant State Health Commissioner of Virginia
RICHMOND, VA.

The careful student of sanitary progress in the United States to-day is early impressed with the great contrast between the sanitary conditions in country districts and those in the cities. Recent years have witnessed great progress in the cities. Effective health departments have been organized, and the effect of measures such as the supervision of water and milk-supplies, the visiting nurse and the tuberculosis dispensary, medical inspection of schools and the accurate control of contagious diseases has been so pronounced as to place their work on a firm basis, and to insure its continuance and extension. While much remains to be done in the cities, the foundation has been laid and the methods of work more or less standardized. It is not too much to say that we are within sight of the solution of many of the problems of municipal sanitation.

While these facts are true of the cities, in those states with which we are familiar no such condition exists in the country districts. They remain as they have been for years, without efficient organization, depending on the methods and beliefs of thirty years ago. In only a few states is there adequate supervision of the rural communities; only a few states require the reporting of even the most dangerous of contagious diseases, and in most cases what activity there is in the country districts is confined to the control of smallpox, diphtheria and scarlet fever, with occasional attention to a flagrant nuisance. The vast contributions of modern science to the prevention of disease are for the most part lost to the people of the country for the lack of organization and education. There are, of course, isolated exceptions to this statement, such for instance as the wonderful work of the Pennsylvania Department of Health in connection with tuberculosis in rural districts, but for the most part conditions are as stated.

The reasons for this contrast are, in the main, perfectly obvious. There is in the first place a greater survival of the individualistic idea of life in the country than in the city. Government touches the life of the individual in the country to a limited degree only. His personal liberty, so called, is seldom invaded. He is, and he considers himself to be, a law unto himself. In the city the communal idea prevails; no man lives unto himself alone; government is at the elbow of every citizen. In the second place, the very isolation of the country makes it almost impossible in the circumstances to educate the country people in the importance of health measures. A single successful campaign against measles or diphtheria or impure milk will generally convince the people of the city of the importance of health measures. As such a campaign is difficult or impossible under present conditions in the country, education comes more slowly and the support of health measures is always more doubtful. In the third place, the contrast between country and city is largely due to the fact that health measures are more obviously necessary in the city than in the country. The crowded city demands health protection. Where our nearest neighbor lives half a mile away he may suffer from a wide variety of diseases and we may never feel the danger, but

where we are separated from contagious disease only by the partition wall of an apartment house, we feel the necessity for and yield more readily to preventive measures.

The explanation for this contrast, however, is not its justification. The country, no less than the city, needs health education. The country, even more than the city, stands in need of fundamental health precautions. The very mass of disease in the country districts of itself requires that this problem be attacked, but the bearing of rural sanitation on the health of our cities is perhaps a still more immediate reason why our point of attack should be shifted. The health of the city depends in a large measure on the health of the country. Practically all the food-products of the city come from more or less remote country districts. A single case of typhoid fever on a dairy farm may, under certain conditions, infect a whole city, and emphasize to all the intimacy of the sanitary connection. In the same way, close intercourse between cities and the country renders the former particularly liable to infection from the latter. Our experience in Virginia, which is doubtless borne out by that of other states, has convinced us that the prevention of smallpox in the cities is very largely dependent on the close inspection of smallpox in the country, since most cases of this disease are brought into the cities from rural districts or small towns. Then, again, there is a crying need for better rural sanitation because of the more or less general residence of city people in the country during vacation time. We have found in Virginia that the country boarding-house is one of the great sources of our typhoid fever, and many of the cases which appear in the cities after vacation can be traced directly to the bad sanitation of country resorts. If, therefore, the health of the cities is to be improved, the health of the country must also be bettered. And if the nation is ever to stamp out disease, it must be by a general attack in both the city and the country.

In addition to the crying need for such work rural conditions offer to the scientific sanitarian the attraction of almost unparalleled opportunities for research work in the transmission of disease. In typhoid fever particularly, we in Virginia are firmly of opinion that the key to the eradication of our summer typhoid is to be found in the country. To trace the means of dissemination of typhoid bacilli in a city, with its manifold sources of food-supply, the complication of the milk-supply, with daily contact between thousands of persons any one of whom may be in the incubative stage of the disease or may be a typhoid carrier, and with the constant temptation to attribute the infection to the water-supply, is beset with so many difficulties as to make it almost hopeless. The best that can be done is to draw general conclusions from the study of large groups of cases, and even here it is difficult to exclude the general factors of flies, milk and water.

In the country, conditions are very different. Given a country district free from typhoid for several years, the first case is easily discovered, and the transmission of the disease may often be worked out with mathematical accuracy. Water and milk are, of course, easily excluded; flies may be considered with some accurate idea as to their importance as a factor in transmission; and the actual amount of contact resulting in infection may often be determined exactly. We have been able to do this in Virginia in a number of instances with results of the greatest interest. This work extended over a large area, and, combined with careful statistical

* Read in the Section on Preventive Medicine and Public Health of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

studies will throw more light on the city problem than can be obtained in the city itself by any means known at present.

Nor is typhoid the only disease which can be advantageously studied in the country. We have found the study of the transmission of smallpox in rural districts to be of great interest by reason of the fact that the time, place and manner of contact can be worked out with ease and certainty. Diphtheria and scarlet fever, studied case by case in rural districts, should throw great and much-needed light on the transmission of these diseases.

It may not be amiss at this point to call attention to the value of the case method of study of infectious diseases in rural work. A personal visit to each patient, the collection of the data needed at the place where the disease occurred, and the interpretation of the epidemiologic evidence in the light of the other information secured by a visit to the premises, offers by far the most promising method for the solution of the problems now pressing for solution.

The rural districts, however, offer even greater possibilities in practical prevention than as a field for studies in the transmission of disease. The separation of individual cases, the slowness and freedom from complication of the intercommunication, render health work in the country much easier than in cities. With trained men, and an adequate system for promptly collecting and studying morbidity statistics, preventive work in rural districts may be made to have the efficiency of a well-oiled machine.

Even here, however, it is obvious that all the phases of sanitation which arise in the study of rural conditions cannot be studied fully by the limited force at the disposal of the average state health department. Some limitations must be made and some problems in the country must receive more attention than others. In Virginia we have carefully considered the subject and have concluded that, for the present at least, typhoid fever and hookworm diseases should receive first attention. The reason for this decision will, I think, be obvious to all. Typhoid fever is and will probably remain the greatest single problem of rural hygiene. High as is the death-rate from typhoid fever in the country as a whole, it is highest in the South; and awful as is the toll which most Southern cities pay to this disease, their burden is not so heavy as that of the rural sections of the same territory. Hookworm has been placed beside typhoid fever in this work because we are convinced that hookworm plays a part hardly less important than that of typhoid fever in the South and is essentially a disease of the country.

If we must study rural hygiene for its own importance, and if we must limit our study for the present at least to these diseases which are the most disastrous, we must begin our study on the farm. We should not, of course, omit the small towns, as they offer problems intermediate between those of the city and those of the country. But a study of these towns convinces us that in the main the dangers are essentially those of the farm, and the problem is practically the same in its fundamental aspect as that to be encountered in the country.

The farm is the point of attack, and in the work against the diseases I have mentioned the farm is the unit both in the spread and prevention of infection. Each farm is, to all intents and purposes, a separate community, with its own population, its own problems of sanitation, and its own forces for good and evil. The work we would do for the improvement of rural con-

ditions of sanitation must be done for the improvement of the farm.

Studies of sanitary conditions on farms, such as those of Stiles, show facts that are almost unbelievable in the light of our knowledge regarding soil pollution. These studies have been confirmed by our work in Virginia. We have inspected in the course of our work against typhoid and hookworm diseases thousands of farms, and it is the exception rather than the rule that we find even the most primitive sanitary arrangements in use by the people. The privy, if existing at all, is old, in bad repair and of antiquated design. Its use is confined almost exclusively to the female members of the family, the males relying on still more primitive methods of disposal. The contents are open to the chickens, the hogs, the dogs and the flies, and these agencies are relied on to take care of the small amount of material actually deposited in them.

Water-supplies follow the same general tenor, the wells being usually carelessly dug, carelessly protected, if protected at all, and carelessly kept. The well tops, almost without exception, show wide cracks through which filth is washed at all times into the well; the buckets are handled by all kinds of hands and then carefully lowered into the well for the only cleaning they ever get. The personal habits of the average inhabitant of a rural district are of a character in keeping with the other sanitary conditions. The absence of running water, and particularly hot water, make effectual cleanliness, especially in cold weather, difficult, and the amount of water used per capita per day is exceedingly small.

It must, of course, be admitted that in every rural community there are those of sufficient intelligence, self-respect, and ability to rise above these conditions and to provide themselves with modern sanitary conveniences, but, particularly in regions where the economic standard of rural life is low, these exceptions are few, and for the most part conditions are as I have described them.

Even under these conditions, amazing as it may seem, there are many rural communities which are and have been for many years practically free from typhoid, despite the prevalence of the disease in this country. There are others in which hookworm has apparently never gained a foothold, but the introduction of a single case of typhoid under favorable conditions is sufficient to give rise to a wide-spread outbreak of the disease, and hookworm infection, though slower in its spread, is equally certain to infect the entire community under these conditions.

These conditions, then, fix the problem of the farm, if they do not solve it, and indicate the direction our work must take. The building of a proper privy with its habitual use by every member of the farm community, its regular and frequent cleaning and proper disposal of the material, the safeguarding of the water-supply, and the instruction of the people as to the necessity of obeying the Scriptural injunction to wash before meat, are not of themselves difficult, expensive or revolutionary procedures. Moreover, when we take into account the fact that the carrying out of these procedures will do much to secure the immunity of the inhabitants of the farm from soil-pollution disease, it does not seem that it would be difficult to secure their adoption. When we face the problem in Virginia, however, of putting these measures into effect on hundreds of thousands of farms, scattered over forty thousand square miles of territory, and containing a population of one and a half million, who live under a governmental system which promotes

or protozoan is very much lowered. This would increase the acidity due to bacterial growth.

We must remember also that one factor appears certain as a cause of pellagra, though there are more than one, probably several causative factors. I believe I can show, with some pictures I have, that exposure to sunlight is absolutely one of the factors in the production of the skin symptoms of pellagra. The skin lesions are usually minor and terminal symptoms of pellagra are seldom the important early symptoms of the disease.

In one instance an insane woman had a peculiar habit of keeping one hand in her bosom all the time, while the other one was exposed to the sunlight. The exposed hand developed pellagrous lesions; the other remained absolutely free. In another instance a woman wore a finger-ring on one finger on each hand. A short time after she had developed the disease she pulled the ring off from one finger and continued to expose herself to the sunlight for the benefit of her health, taking buggy rides in the sun. She continued to wear the other ring, until she was sick with a well-developed attack of pellagra. When first seen by me she had a perfectly clear, normal skin under the ring; the remainder of the hand presented a severe form of pellagrous skin lesion.

DR. JAMES W. BABCOCK, Columbia, S. C.: I think that we are all under a debt of much obligation to Dr. Long for his paper, and particularly for emphasizing once more the importance of the presence of amebiasis in pellagra, and furthermore for the observation of the deposit within the spinal foramina, thus giving another theory to explain the presence of the skin lesions.

I think most of us who have studied pellagra for any length of time are beginning to realize that we are dealing with a big problem. The trouble is that each one of us approaches the subject from too narrow a viewpoint. The dermatologist sees in the condition purely a dermatologic condition; the asylum man sees in it insanity, and so on; and each one approaches this big subject in too narrow a way. The observation of parasites in pellagra is an old one, established long ago in almost all the cases that were admitted to the Cairo (Egypt) asylum. Allen, of Charlotte, N. C., last fall demonstrated the almost constant association of amebiasis with cases of pellagra in his section of the country.

I have an associate who sees in pellagra merely an expression of the hookworm disease; and the positive denial by Dr. Stiles that he had ever seen this expression of the hookworm disease does not satisfy this friend of mine at all; it is probable that pellagra and ankylostomiasis will to him always be synonymous. Reference has been made to Dr. Bass' observation of the Wassermann reaction in pellagra. In connection therewith, I think it should not be forgotten that Dr. Howard Fox of New York has studied 30 cases of pellagra with the Noguchi modification and failed to establish the presence of the Wassermann reaction, so we have two observations—one pointing to the presence of a parasite and the other denying it.

Sir Patrick Manson mentions the presence of intestinal parasites in a condition similar to pellagra and warns observers not to associate these conditions as of cause and effect. Manson in the fourth edition of his "Tropical Diseases" says: "The novice in tropical medicine will be greatly puzzled over these cases of beriberi. If he examines the blood of these patients; possibly in a proportion of them he will find *Filaria nocturna* or some other blood worm. Very likely he will then think that the cases are forms of filariasis, and he may construct theories to explain how the filaria produces the symptoms. In some countries, in nearly all cases, he will find the ova of the *Ankylostomum duodenale*. On this evidence he may conclude that these are cases of ankylostomiasis. He had better, however, not commit himself to such a diagnosis until he has ascertained how it fares with the rest of the population as regards these parasites, for he will find that the ankylostomum and the filaria are quite as prevalent outside as inside the hospital and in the healthy as well as in the sick."

It is very important in the treatment of pellagra to remove these various parasites, but I think we shall find out in the

end that the removal of the parasites does not per se cure the pellagra.

DR. SENECA EGBERT, Philadelphia: I would like to emphasize the point Dr. Price has cited about the matter of control. From our experience in Pennsylvania I believe it will pay any of the commonwealths in the south, or anywhere else for that matter, to have enacted a very strict and comprehensive health law, and then, if they can, get a commissioner that has nerve enough to enforce the act wisely and conscientiously, appointing under him county and other local health inspectors. I was very much interested in Dr. Freeman's talk on the work of the county or the farm inspector, for that seems to me an admirable way of carrying out what I was talking about this morning—the matter of popular education—and also to attain our object of improving public health.

We in Philadelphia are interested in this matter of pellagra because, I am told, we have had some cases of the disease in our city hospital, although I have not personally seen them. But you have typhoid fever in the south, as well, and if you can get rid of that at the same time that you are getting rid of your hookworm and your pellagra your gain will be so much the greater.

It seems to me that with the kind of work that is being done by the City of Richmond, and by Virginia, in sending out live, intelligent, up-to-date men who go out into the rural districts and show the people about these diseases and also show them how to rely on the talk of the local doctor, we have the popular education which is needed as a basis; and then with a proper set of health tracts for general distribution and with increasing work, it seems to me your problem down there in regard to the hookworm, pellagra and all of these troubles—typhoid not the least of them—is going to be, not easy of solution, but capable of solution within a shorter time than you or we, perhaps, anticipate.

DR. JOHN D. LONG, Washington, D. C.: My paper may sound misleading as to my intent. The work is somewhat different from any work that has been done in pellagra before, and for that reason I wish to say that I do not mean to pretend or assume in any manner that the pellagra question is solved. I am simply giving the hypothesis on which I worked in Columbia and an outline of the studies that were carried out in accordance with a working hypothesis.

DR. CHARLES W. STILES, Washington, D. C.: I believe in a license system for the privy. Certain of the southern towns (Chapel Hill and Richmond) at present charge householders about \$5 per year license for every privy. The town then furnishes the disinfectant and pails and does the cleaning, the expense for which is covered by the license fees. It seems to me that that is a very excellent system. We must come to the point of view that the privy, despite the fact that "privy" refers to "private"—is not a private institution but a public institution. I believe also in the compulsory privy law which is being introduced in certain southern localities; but there is one factor in the south which we must not overlook, and that is that after we have the sanitary privy introduced we have an element in the male negro population which is going to be difficult to control. The white women now are using the privies when they are present; it will not be a difficult proposition to get the white men to use them; many of the negro women are using them; but it is going to be a very difficult task to teach the negro man to use them. I do not personally believe that there is any way to do this except by compulsion. Eventually we shall have to come to the standpoint in the southern states that an insanitary act means a service on the chain-gang; and eventually, I think, the chain-gang will be the school of cleanliness for the male negro.

DR. ALLEN W. FREEMAN, Richmond, Va.: We have solved an exceedingly distressing condition in Richmond, Va., as regards the privies. We had three years ago some 5,000 open privies, a great many of which were never cleaned at all; they were mostly in territory which had only recently been annexed to the city. Dr. Levy, the health officer, with his customary energy, had an ordinance passed requiring every privy in the city to be rebuilt in accordance with standard specifications which were drawn up and printed. Within six months some 5,000 privies were built or remodeled. They are cleaned

regularly by a city officer. The cost of cleaning is a charge on the property and is collected just like any other tax. I am glad to say that the reduction in typhoid following this procedure was immediate. This reduction did not follow an enormous amount of work on the milk-supply, on other foods and on the individual cases to secure the disinfection of infectious material at the bedside. The typhoid death-rate, which had never been below 44 per hundred thousand per annum, dropped last year to 24; and we hope to see it go still lower.

CERTAIN LEGAL ASPECTS OF DOMESTIC QUARANTINE*

HENRY BIXBY HEMENWAY, A.M., M.D.
EVANSTON, ILL.

The word "quarantine" was originally used to designate the forty days of Lent. Then it was applied in the English law to the forty days after the death of her husband, during which a widow had the privilege of remaining in her husband's mansion house, and during which time her dower was to be assigned. Next we find the term employed with reference to the forty days during which a vessel might be detained without intercourse with the shore, after arrival from an infected port. After it was learned that forty days' isolation was not invariably necessary, the original signification was dropped, and the word came to refer only to the isolation of the vessel. The same idea, and the same methods, applied to protection at a land frontier; and later to the isolation of persons, or places contaminated with infectious disease. It is interesting here to note that syphilis was a subject of land quarantine in Europe during the earlier years.

The present domestic quarantine is no more anomalous as to original signification, than it is as to either law or science. We know well that in the case of yellow fever, for example, it is far less necessary to prevent intercourse between the patient and healthy individuals, than it is to exterminate the *stegomyia* mosquitoes. A typhoid patient is not properly isolated if his discharges are thrown into the public sewage system before disinfection. The complete disinfection of these discharges must be an integral part of such quarantine, yet that fact is not generally realized by the citizens of this country. As to the legal side, we have made practically no advance in the last hundred years. Neither the rights nor restrictions of either state or individual, are much more clearly recognized to-day than they were when this nation was born. Just as in industrial pursuits, to preserve the same general line of action, we must alter our methods to conform to recent scientific advances, so in law we must alter our statutes and institutions, to conform to the decisions and discoveries of a progressive people. Fundamental law must be flexible, and change in form according to conditions. Is it not time that our archaic practice as to quarantine should be critically examined and revised?

The first step from absolute monarchy is the establishment of institutions. Institutions may be safeguarded by constitutions. Though ours is a constitutional government, there are certain institutions which have survived which are more dictatorial than constitutional, and quarantine is one of these. It overrides all constitutional rights. Though we are supposed to have guaranteed to us the right of liberty, any person may

be imprisoned by a health department, without a previous trial, and without even having a formal complaint lodged against him. Is a retail merchant a criminal simply because a patient suffering with a mild form of smallpox happens to come into his store to make a purchase? Yet such a dealer may have his store closed, and he himself imprisoned, and he is practically without redress.

It is well recognized that the greatest liberty for the individual, as well as the greatest safety for the nation, is to be found in the observation of constitutional provisions. Whenever two courses are open it is our duty therefore to take the constitutional route. It is sometimes necessary, however, to suspend constitutional protection. Thus when the spirit of anarchy settles on a community, and a mob rules a city, the slower operations of ordinary law are unable to cope with the danger, and martial law must be declared. So too, a man's house is his castle, and the stranger may not enter without permission; neither must he take therefrom aught which is not his own; but when the house catches fire, no portion is so private that those who are fighting the fire are restrained thereby. It is contrary to both constitutional and statutory law to kill a human being; but "self-preservation is the first law of nature," and it is not deemed criminal if the killing be in self-defense, or, as in the case of a policeman in the line of duty. Self-preservation on the part of the community may demand the imprisonment, either at home or elsewhere, of an individual afflicted with, or exposed to, an infectious disease. If the ordinary liabilities were more clearly defined in the statutes, and the duties of health officials were thus definitely prescribed, much possible opposition would thus be removed, and even in those occasional extraordinary emergencies when it is necessary for the health officer to take martial command, he would have more of the confidence of the citizens, and more active support. The present system is unconstitutional, un-American and despotic in many states. Whether the powers are used for good or bad, whether as a help to the community, or a means of oppression, depends entirely on the individual officer. It is true that the power is seldom abused, but we must remember the possibility. During the old Tweed régime in New York City we are told that the health department was systematically used as a tool for collecting blackmail.¹

There is another form of abuse of sanitary authority which is more or less common. It forms an argument against boards of health, as compared with health commissioners; and it is an evidence that health officials should not be engaged in private practice. Here is an illustration: A widow in Clark County, Illinois, sold milk in a neighboring village. Her son came home from Brazil, Indiana, sick with typhoid fever. The mother nursed him, still continuing in the milk business. The local board of health consisted of three physicians, unpaid. One of these was the attendant on the typhoid patient. Knowing that the widow was dependent on her business for support, he was reluctant about forbidding her to sell the milk. The other members of the board hesitated to act, lest their motives might be misunderstood, and jealousy charged. After some thirty cases of typhoid had occurred on her route, the sale of milk was stopped, and no further cases occurred.

It is true that we have at present a check on the abuse of the power now possessed by health officials, in the form of court supervision, but that check may very easily

1. Autobiography of Andrew D. White.

prove a source of annoyance, or oppression on the health departments, and the ends for which they are created be thereby defeated. For example: Suppose that the members of a household are quarantined for malaria. Every sanitarian knows that in the presence of the anopheles such a family is a source of danger to the community, and the individuals should be restricted as to liberty. It would not be difficult, however, in most communities to find physicians who have the respect and confidence of the citizens, and who would deny in court the relationship of mosquitoes to the disease, and who would assert that malaria is not infectious like yellow fever, but that it is due to some indefinite miasm which is present in certain localities. Under such conditions it would not be strange if a judge should decide that the disease is not infectious, and he might even render a judgment for damages against the health officer. In the absence of statutory provisions to the contrary, the opinion of one physician is as good in law as that of another, and a health officer is only a physician under such conditions.

The three great objects of government are: The maintenance of national existence; the maintenance of right or justice; and the public welfare.² Health departments have to do with each of these objects. Their powers are of the nature technically called police powers. While the Federal government may exercise certain of the functions of health administration in the United States, *authority* of action rests in the individual states. Certain powers may be delegated by the states to the municipalities. These delegated powers are always subordinate to state action. Thus, among the powers of cities and villages granted in the statutes of Illinois we find:³ "Sixty-seventh.—To appoint a board of health, and prescribe its duties;" and "Seventy-eighth.—To do all acts, make all regulations, which may be necessary or expedient for the promotion of health, or the suppression of disease." Acting under these provisions the City of Chicago passed an ordinance making vaccination obligatory as a requisite for attending the public schools. The Supreme Court, however, in *Jenkins vs. Board of Education*,⁴ held that the legislature of the state had not made such a requirement, and that it had not delegated the power to do so to the city.

In order more perfectly to control the collection of manure in the City of Chicago, an ordinance was passed and a contract made, after advertising for bids. One Landberg, who had made a business of collecting and selling such manure, was thereby thrown out of his occupation. He objected, and the Supreme Court found the ordinance unconstitutional, on the ground that it created a monopoly, and interfered with legitimate business. The city may regulate such occupation, by license or otherwise, but it may not, without specific power granted by the legislature, create monopoly, or destroy a private enterprise.⁵

McGehee⁶ holds differently, saying: "The property interests in the noxious materials must be subordinated to the general good." He refers to *California Reduction Co. vs. Sanitary Red. Works*, 199 U. S., 306, and *Gardner vs. Michigan*, 199 U. S., 325.

In these cases the matter of monopoly was distinctly considered as well as the interference with private business. Both of these cases were mentioned in the brief of the attorneys in the Landberg case. Since these decisions

were from the highest court in the land, it seems strange that in differing from the Federal court the Illinois court did not specially mention these decisions in its opinion. It is the contention of the Chicago Department of Health that the present method does injure the community, and that the method proposed in the ordinance was necessary to safeguard the interests of the citizens.

The general rule governing such matters is thus stated by Freund.⁷

Under the principle of local self-government local authorities cannot be vested with powers necessarily exceeding their territorial jurisdiction; those matters therefore which equally affect the people of the state at large, and cannot be confined locally, must be reserved to the state legislature. Moreover, the inauguration of a novel policy in matters of safety and health, the prohibition of articles of consumption possibly but not undoubtedly injurious to health, the establishment of monopolies, the restriction of the right to pursue established avocations, may under circumstances be conceded to the legislature of the state, but cannot be introduced by local authorities under mere general grants of power.

Such a limitation of municipal power is reasonable. If left to the individual municipalities, confusion, and lack of protection is likely to arise, and local feeling may lead sometimes to excess of reasonable action. Thus adjoining municipalities may establish very different regulations as to quarantine. It is necessary, therefore, that there be a general supervision, and coordination.

In spite of the delegation of powers to cities and villages in Illinois, as cited above, we find that as amended in 1907 the Revised Statutes,⁸ say of the State Board of Health that it "shall have supreme authority in matters of quarantine, and may declare and enforce quarantine when none exists, and may modify or relax quarantine when it has been established." Such a provision would be all right if it were made more definite, but there is nothing in the statutes making it requisite on any one to report infectious diseases to any one, specifying what diseases are to be quarantined, or defining in the least how, or to what degree such quarantine is to be exercised. It puts into the hands of the executive of the board almost unlimited power. Some time ago in a dairy district supplying Chicago with milk, families were quarantined for scarlet fever. A representative of the state board appeared and abolished the quarantine. If the law is constitutional, he had the undoubted legal right to do so autocratically. There was no appeal.

It is possible that such a law as that just mentioned might be declared by the court unconstitutional, for the reason that it gives to a man, or body of men, an arbitrary power, without limitation, and violates the provisions of the fifth and fourteenth amendments to the Federal Constitution. Health boards, and officers, have only executive power. They must not act in a legislative capacity. There is nothing in the statutes of the State of Illinois which limits quarantine of human beings to infectious, or contagious diseases. Though animals afflicted with contagious diseases are especially mentioned in the statutes, and provision is made against the spread of hog cholera, glanders, and cattle fever, so far as the state statutes are concerned human beings are permitted to communicate their diseases to others with impunity. On the other hand, there is nothing in the statutes which would prevent the state board of health, through its executive officer, from quarantining a man afflicted with any disease, nephritis for example, though

the common law practice might prevent such action. Still court action is not rapid, and a corrupt politician might thus gain the temporary seclusion of an opponent.

As set forth by Prof. Goodnow⁹ there are three ways possible by which a nuisance may be determined; by the common law, by legislation, and perhaps by executive action when so authorized by legislative enactment. In common law, the courts are supreme, and boards of health have no power to enlarge common law nuisances. Smallpox is a common law nuisance, but malaria is not. As to the right of legislatures to enact such laws, there is no question. The restrictions on boards of health, or health officers, are not so generally recognized by sanitarians. In the most excellent decision of *Pott vs. Breen*,¹⁰ the Supreme Court of Illinois said of the State Board of Health:

It had and could have no legislative power. Its duties were purely ministerial, and the provision of the statute authorizing the board to make such rules and regulations as it should from time to time deem necessary for the preservation or improvement of public health cannot be held to confer that broad discretionary power contended for.

And:

We are of the opinion that the powers of the board are limited to the proper enforcement of the statutes, or provisions thereof, having reference to emergencies requiring action on the part of the agencies of government to preserve the public health and prevent the spread of contagious or infectious diseases.

And again:

Its duty to recommend legislation is repeated more than once in the act in connection with specifications of the powers and duties of the board.

The Supreme Court of Wisconsin gave a similar opinion in *State vs. Burge*.¹¹

The Minnesota Supreme Court, in *State vs. Young*,¹² said:

It is a principle not questioned that, except where authorized by the constitution as in respect to municipalities, the legislature cannot delegate legislative power—cannot confer on any body or person the power to determine what shall be law. The legislature only must determine this.

So we find in *Dowling vs. Insurance Company*¹³ that it was an unconstitutional act when the legislature attempted to leave to the insurance commissioner the decision as to what form of a policy must be used. So too in *Schaezlein vs. Cabaniss*¹⁴ it was illegal to leave to an executive officer the power to determine the particular form of appliance which should be used in factories to limit the dangers therein, and making it compulsory on the owners to comply with his orders.

Freund summarizes:¹⁵

It cannot be left to an administrative officer to determine conclusively the existence of a danger, and the choice of measures to be taken against it, since that would involve an unconstitutional delegation of legislative power.

The fifth amendment to the Federal Constitution provides that no person shall "be deprived of life, liberty, or property, without due process of law; nor shall private property be taken for public use, without just compensation." The fourteenth amendment says in

Section 1: "No state shall make or enforce any law which shall abridge the privileges or immunities of citizens of the United States; nor shall any state deprive any person of life, liberty, or property, without due process of law."

What is "due process of law?" Pomeroy says:¹⁶

Due process of law implies primarily that regular course of judicial proceeding to which our fathers were accustomed at the time the Constitution was framed; and, secondly, and in a subordinate degree those more summary measures which are not strictly judicial but which had long been known in the English law and which were in familiar use when the Constitution was adopted. These summary measures generally, though not universally, form a part of that mass of regulations which many writers term "Police," and which relate to the preservation of public quiet, good order, health, and the like. . . . The summary measures which may form a part of due process of law are those which have been admitted from the very necessities of the case to protect society by abating nuisances, preserving health, warding off imminent danger, and the like, when the slower and more formal proceedings of the courts would be ineffectual.

In *Murray's Lessee vs. The Hoboken Land Company*,¹⁷ Mr. Justice Curtis says:

Though due process of law generally implies and includes actor, reus, judex, regular allegations, opportunity to answer, and a trial according to some settled judicial proceedings, yet this is not universally true. There may be, and we have seen that there are, cases under the law of England after Magna Charta, and as brought to this country and acted on here, in which process in its nature final, issues against the body, lands and goods of certain public officers without any such trial.

Due process is not necessarily judicial process.¹⁸ The term, therefore, is now frequently applied to legislation. the underlying principles being that all persons interested may have an opportunity of being heard, and that the legislation does not represent arbitrary acts of government.¹⁹

An arbitrary statute is not due process.

The just cause of legislation is the legitimate function of government. A statute not supported by such cause is not due process.²⁰

Practically the present system of judicial control over legislation has meant in many cases that unless all three departments of government are convinced of the justice and reasonableness of a radical change in social or economic policy it cannot become embodied in principles of law.²¹

A recognition of these principles, in the place of restricting the liberty of action for health officials, really increases their power. A man walking on uncertain ground must go carefully. When assured of its safety, he may step boldly and with speed. If the infectious nature of a disease is not legally established, no matter how sure the official may be, he is liable to be blocked by *habeas corpus* proceedings. He must then establish before the court the correctness of his diagnosis, the infectious nature of the malady, and that the measures taken are both reasonable and necessary. If he fails to satisfy the court on every point, the case is lost.

General rules and regulations have not the same standing as statutes.²²

Such rules and regulations should only be issued in conformity with the clear and evident intent of the

statutes. In *Kirk vs. Wyman, et al.*,²³ before the Supreme Court of South Carolina, we find this statement:

From this it follows that boards of health may not deprive any person of his property or his liberty unless the deprivation is made to appear, by due inquiry, to be reasonably necessary to the public health; and such inquiry must include notice to the person whose property or liberty is involved, and the opportunity to him to be heard, unless the emergency appears to be so great that such notice and hearing could be had only at the peril of public safety.

In this case the court held that the health department exceeded its authority in removing a case of anesthetic leprosy to a pest-house. Sanitarians would agree that typhoid and malarial fevers are infectious, dangerous to the community, and legitimate objects for some form of quarantine. These facts have been recognized for some time. However, for a board of health, or a commissioner of health so to declare, or rule, would in fact be an act of legislation exceeding his authority. It would be giving neither due notice, nor opportunity to be heard. The quarantine of such a case could hardly be justified on the ground of an emergency, for the general conditions have long been known, without any attempt on the part of the executive to secure proper legislation. The case of epidemic poliomyelitis might be different. The disease has generally been considered non-infectious, and therefore not a proper object for quarantine. The fact has only recently been demonstrated that it is infectious. The statutes should be sufficiently elastic in construction to permit health officials under such conditions to control and quarantine such a disease until such time as the legislature could reasonably be expected to act. If the health executive has placed the facts properly before the legislative body the responsibility rests on the law-makers, and the executive no longer has the right, in the absence of new facts, to declare such a disease quarantinable. So too, some well-known disease, which there seemed no reasonable probability would ever enter the particular community, might not have been mentioned in the statutes, and its appearance would constitute an emergency. In the case of *Jenkins vs. Board of Education*²⁴ it seems that the Commissioner of Health had issued orders declaring smallpox epidemic. The court held that he had exceeded his authority.

There is nothing in the nature of an emergency in the occasional recurrence of the well-known disease of smallpox in a city like Chicago, which may not be provided for by general rules and regulations prescribed by the legislative authority of the city.

It must be recognized that in all these litigations the health department runs the risk of defeat, and so of loss of prestige; and that even when the final decision is on the side of the health service, adverse decisions in the lower courts involve loss of time as well as expense.

The statutes of the states are generally silent on the authority of diagnosis, and in the cases which have come to court there is some difference of opinion. An infectious disease is a nuisance. In *Kenedy vs. The Board of Health*,²⁵ it was said:

The determination that a thing is a nuisance is final under the Pennsylvania statutes, and in a suit to collect expenses or abate the nuisance the defendants could not offer evidence to show that there was no nuisance.

In *Brown vs. Purdy*,²⁶ as to a question of the diagnosis by the health officer, it was held:

If there was any case for his judgment, or any fact or appearance or symptom as to which a question of smallpox or not could arise, his determination was final as to the legality or propriety of removal.

On the other hand, in *Miller vs. Horton*,²⁷ a board of health was held liable for the killing of a horse, at the order of the commissioner of contagious diseases of animals, who had decided that the horse had glanders. His diagnosis was disputed in court by unofficial testimony, and the court took on itself the responsibility of deciding that the horse did not have glanders. If the responsibility of diagnosis is not placed on the health officer, it must be remembered that the legal diagnosis must be made by the court, which is not supposed to have a medical education.

It will be noticed that in *Brown vs. Purdy* there is another question, namely, the authority of the health officer to remove a patient afflicted with an infectious disease. In Maine a police officer and the city physician, acting under the direction of the mayor of Bangor, after seeking a more peaceable entrance, broke into a house, and took a child sick with smallpox out of its mother's arms, to a hospital. Action for trespass was dismissed, because the statute permitted health officers of a town in which a person was affected with a disease dangerous to the public health to remove such a person to a separate house; but the court called attention then to the fact that such power must be clearly given in the statutes.²⁸

In an early case in Maryland,²⁹ the court held that the health officer must send a patient to the hospital if in his opinion such a course were necessary, and it further held that the health officer alone could decide how much it was necessary to do, and the captain of the boat on which the smallpox had been found must pay the bill. It is doubtful if a court to-day would go so far. In *State vs. City of New Orleans*,³⁰ the legislative power of the state to decide where smallpox patients were to be treated, was upheld. As opposed to the authority of the health officer to remove a patient against his will, in *Boom vs. City of Utica*,³¹ the court said: "A person sick of an infectious or contagious disease in his own house, or in suitable apartments at a public hotel, or boardinghouse" is not a nuisance.

In *Kirk vs. Wyman*,³² the court further uses this expression:

Inasmuch as it is the province of the legislative branch to determine what laws and regulations are necessary to the public health, statutes and regulations made and measures taken under such statutes and intended and adopted to that end are not subject to judicial review; but the courts must determine whether there is any real relation between the preservation of the public health and the legislative enactment, or the regulations and proceedings of boards of health under authority of the statute.

There is an old adage: "In time of peace prepare for war." If we wait for an epidemic before the due process of law, we may find our hands occupied with the preliminary preparations, when we should be engaged on the firing line. That has been the experience in the beginning of most great epidemics. Due process includes the argument of the defense. Education is a portion

of that due process. The education is not complete until a decision is reached. The decision may be in the legislature. If it is not there, it is likely that it will be in a court. For the benefit of each side the decision should be reached when time is not an important element. If the conclusions are definitely stated in legislative enactment, the fight in the epidemic will not be along the whole line, but in a limited section. On the other hand, in the absence of such definite statutory enactments, long usage may give a health officer a confidence which is unwarranted, and he may suddenly wake up, as the result of a court decision, to a realization of the fact that his method is illegal. Lieber³³ calls attention to the fact that institutions, though not viciously conceived, may become injurious. They may become hollow and like the empty boxes in an ill-managed house, become catch-alls for rubbish, and thus nuisances. McGehee³⁴ advises that, when in doubt as to authority, health officials have the matter determined in advance by the courts, for self-protection.³⁵ It matters not how desirable an object may be of attainment, if the method used is even slightly illegal, it should be abandoned, and a more just way found. In *Potts vs. Breen*,³⁶ the court admitted the advisability of vaccination, and pointed out the legal method of its attainment. In *Boyd vs. United States*,³⁷ Mr. Justice Bradley says:

Illegitimate and unconstitutional practices get their first footing in that way, namely, by silent approaches and slight deviations from legal modes of procedure.

A person who knowingly and willfully exposes another to infection is in fact a criminal and he is also liable for civil damages. Intentional wrongdoing is not necessary; all that is necessary to be shown is that due precautions have not been used.³⁸ To-day, many cases of infectious disease are kept hidden, through fear of placards, or of quarantine, or of loss of trade. In many mild cases no physician is employed for these reasons, and because the persons involved do not recognize their responsibility to the community. In this way not only is the danger to the community increased, but very often valuable time is lost, as in diphtheria, and the life of the patient is sacrificed by the delay. A statutory enactment is educational as well. The parent is no longer able to quote the conflicting theories of physicians, of whose relative authority and competence he is incompetent to judge.

Without considering the legal responsibility of the community to care for those quarantined; or the duty of the health service to pay for articles seized, or destroyed; or the liability of a community to those who innocently contract an infectious disease through the inefficiency of a health department; or the desirability of an enactment making school inspections obligatory; it is suggested that much of our present confusion, and

possible inefficiency, will be relieved by securing certain statutory enactments.

First: The statutes should definitely specify certain diseases as infectious, and require that they be reported to proper officials.

Second: The hiding, concealing, or neglecting to report such diseases, or a suspicion of their presence, should be made a misdemeanor, punishable by fine or imprisonment.

Third: The knowingly or wilfully exposing a person to infection, through neglect of the principles of quarantine, should be specifically made a misdemeanor, and punishable by fine or imprisonment.

Fourth: The statutes should make it obligatory on health officials to maintain quarantine, and the minimum requirements of such quarantine should be stated. It must be recognized that the problems of a thinly settled community are very different from those of the densely populated cities, and power should be given to local authorities to make more stringent regulations in the form of ordinances. In such statutes it must be remembered that the essentials of efficient quarantine differ according to the character of the diseases.

Fifth: The legal status of disease carriers, especially typhoid and diphtheria, should be definitely stated. They should be obliged to report regularly to the local health officer (though not for treatment), and should by law be restricted from engaging in certain occupations, such as around dairies, or restaurants, or other places where they would be likely to spread the disease. No such person should be given a clear bill of health, until after examination by the legal guardian of the public health he shall be found free from evidence of disease.

Sixth: The diagnosis of the health official should be considered final, subject only to an appeal to his superior. In a recent case in California, in one of the lower courts, physicians were permitted to testify to fact, not expert opinion, in the diagnosis of disease. It was recognized that they used their expert training to make the diagnosis, but having made it, the court accepted it as fact, not opinion. There is no reason why a man should not testify that a disease is typhoid, more than that he should not testify that a certain animal is a horse. In the absence of such a declaration on the part of the legislature, the diagnosis of a competent health officer may be off-set in the courts by the testimony of an irresponsible private physician. Mistakes of diagnosis may occur, and private individuals be injured thereby, but the danger to the community will justify such a provision. *Salus populi est suprema lex.*

Seventh: In the case of an infectious disease it should be obligatory on the local health officer to give to the persons responsible for the care of the patient printed instructions, or orders, regarding the case, including the care of discharges from the patient, and violations of such orders should be punishable. Such instructions should not be left to the attending physician, unless he be official.

Eighth: Release from quarantine should be only on the signed permit of the official. School boards should not be permitted to accept such certificates from the attending physicians, unless they be official.

Ninth: Health officers should be obliged by the statute to keep as complete a record as possible of the circumstances of the infection, and trace, if possible, the source of infection, and the means of the communication. For legal, as well as scientific reasons, such a record should show the result of bacteriologic or blood

37. 116 U. S. 616-635.

38. *Holland vs. Bridenstine*, 104 Pac. R. 626, a physician was assessed damages for communicating gonorrhea by the use of unclean instruments.—Supreme Court of Washington sustained. A railroad ticket agent worked while suffering with smallpox. Passengers contracted the disease from him, and were awarded damages against the company (Court of Civil Appeals of Texas, approved *M. K. & T. Ry. Co. vs. Raney*, 99 S. W. Rep. 589).—Damages awarded against a city for typhoid fever from an infected public water supply (*Milnes vs. Huddersfield*, L. R. 10 Q. B. Div. 124).—According to *The Engineering News*, April 28, 1910, p. 906, the Civil Court, London Assizes, recently awarded damages to the amount of \$2,430 against a milk dealer for typhoid fever contracted by a user of the infected milk. The principles are the same as those holding railway companies specially liable for injury to stock when the company neglects fences. Also see *City of Pekin vs. McMahon*, 154 Ill. 141, and the sheep case of *Herrick vs. Gary*, 65 Ill. 101.

examinations, and whether such tests were made officially, or by private practitioners.

Tenth: The statutes should give to the health officials authority to remove a person sick with an infectious disease to a hospital, or other suitable place for treatment and isolation. Such removal should be made discretionary, not obligatory.

Lastly, provision should be made for emergencies, and health officers should have certain liberty of action in the presence of danger, which is not provided against in the statutes.

701 Davis Street.

ABSTRACT OF DISCUSSION

DR. JOHN H. WHITE, New Orleans: There was a time when we were compelled to resort to regulations in health matters, rather than legislation, because of the very scanty knowledge we had of the methods by which the various diseases were diffused in our communities. Fortunately that time is passing. All legislation must be carefully framed so as not to bring the health officer up against a stone wall. There must be some loophole left for him to use discretion. The state from which I come practically entrusts its state board of health with the power to legislate—a power which is absolutely unconstitutional, and which will be thrown down any time that anybody chooses to take it into the supreme court, and leave the boards of health helpless to defend themselves, even though they have been doing exactly the right thing.

Dr. Hemenway's remark about the confidence that the health officer will have when he is backed by law and not by regulation appealed to me very strongly. He can go forward then, because his backing is in line with the law of the land. I have had some experience of my own; by depriving men of their liberty—imprisoning them in box-cars to keep them from disseminating yellow fever—with absolutely no law or regulation behind me, I have run the risk of being deprived of my own liberty; and I have done it so much that had I not passed the statute of limitation on this matter I would be rather afraid to live in the state now.

The health officer, in any community which is able to pay a health officer, should under no circumstances follow a private practice. No matter how honest a man may be, he will have an unconscious leaning, if nothing more, toward his own patients; he will feel averse to getting them into trouble. But in a country village that is utterly unable to pay the health officer more than \$100 or \$200 a year, the officer is obliged to resort to the practice of medicine, and the village must do the best it can.

The one thing that stood out as one of the most salient points to me, however, was this matter of the insufficient authority of the health officers and others, evidenced in our own work in immigration service, to make a diagnosis and to have it legally sustained. I have had the courts take away a case of trachoma on the evidence of men who said it was not trachoma because there was no law to say that the decision of the medical officer in that case was final. The plague was announced in the city of San Francisco; a judge on the United States bench declared from the bench that he had had evidence submitted to him sufficient to justify him in the assertion that there was no plague in the city of San Francisco and offered to put Kinyoun in jail for saying that there was plague in San Francisco. We can have no stronger evidence than that of the necessity of having law back of the health officer in every particular in which law can be substituted for regulation.

I know of many instances in which the law against concealment of disease by physician or patient prevented disaster in the endeavor to wipe out disease. Without the ability to force the unwilling to tell the truth, it is almost impossible to wipe out an epidemic in a community. With that ability, the health officer's hands are held up mightily. Such laws as Dr. Hemenway advocates, adroitly framed, leaving as much discretion to the health officer as is consistent with the constitution, and enacted in every state in the Union, would

double the capacity of the health authorities for the extirpation of disease.

DR. W. A. EVANS, Chicago: If Dr. Hemenway will read the *Engineering News* for May he will find reference to a civil suit for damages when the act committed was selling milk, which spread typhoid fever. Health officers do not know enough law, and courts take peculiar views on health questions. The Jenkins and Landberg cases are in court. Each of these was decided on the facts and in neither were the facts before the court, or rather each was an expert opinion on the facts and neither witnesses as to the facts nor expert witnesses had been heard. All health department work is based on police power. No health case has had its day in court until the facts have been heard.

DR. W. F. SNOW, Sacramento, Cal.: Vaccination laws have been mentioned during this discussion. I received this morning a letter which states that the vaccination case in California was decided in favor of the State Board of Health. The district courts had decided that our compulsory law was unconstitutional on account of class legislation and that the State Board had no authority in the public schools—the decision as to when vaccination was necessary resting solely with school trustees. The appellate court has just reversed this decision of the lower court and declared the law to be constitutional. The state board now intends to proceed with its enforcement.

DR. HENRY B. HEMENWAY, Evanston, Ill.: The courts have certain methods of procedure which may hardly be gotten around; and the supreme court considers the questions of law, rather than the questions of fact.

VARIATION OF DOSAGE DEPENDENT ON THE METHOD OF ADMINISTRATION*

ROBERT A. HATCHER, M.D.

Professor of Pharmacology, Cornell University; Member of the Council on Pharmacy and Chemistry of the American Medical Association

NEW YORK

This paper is merely a preliminary report intended to call attention to the necessity for the systematic investigation of the rate of absorption of different drugs after different modes of administration and the ratio of absorption to excretion and destruction, and also to one of the methods which may be employed in investigating the subject. Different drugs will require different methods of procedure, and in all cases various species of animals must be employed before we can transfer the results to man.

It is well known that the toxicity of certain drugs varies with the mode of administration, but the exact cause of this variation has not been studied sufficiently in many cases, though it is obvious that the therapeutic dose must usually vary in much the same way that the toxicity does. A large number of experiments will be required to determine the comparative activity of the various potent drugs administered in different ways, but until such determinations have been made with far greater accuracy than has been done with most of them, prescribing must lack that degree of precision which we are coming to demand in every branch of medicine.

It has been said that dosage is the most vulnerable part of therapeutics, yet the one on which the healing art

* From the Laboratory of Pharmacology of Cornell University Medical College. Presented at the International Congress of Medicine and Hygiene, Buenos Ayres, May 25, 1910. Certain facts presented in this paper were stated in a paper read at the meeting of the American Society for Pharmacology and Experimental Therapeutics, Boston, Dec. 29-30, 1909. These will be presented in greater detail in subsequent papers from this laboratory.

mainly depends, and since the correct dosage depends on the rate of absorption compared to that of excretion and destruction, it is obvious that we should have a fairly accurate knowledge of these processes, but reference to the literature will show that our knowledge of the subject is fragmentary in the extreme.

Thus, many of the leading text-books on pharmacology are silent regarding the rate of absorption and excretion of such important drugs as digitalis, and the questions of the absorption, excretion and destruction of the various members of this group have been neglected almost completely by pharmacologists.

Maurel¹ has determined the fatal doses of numerous drugs for different animals by various modes of administration, but his experiments, with strophanthin at least, have little bearing on the therapeutic dose for man. Experiments made in this laboratory during the past three years show that the absorption of the different drugs belonging to the digitalis group from the alimentary canal of animals is very variable. The variability is extreme in the case of strophanthin and amorphous strophanthin as well as in that of crystalline ouabain, or the so-called crystalline strophanthin. The results obtained on animals are supported by observations made on man, and they tend to throw grave doubt on the value of many of the clinical observations made with strophanthin in the past, when the drug was administered orally.

Despite the want of systematic studies of these questions of absorption, excretion and destruction, there is an opinion, which is fairly widespread, that when one knows the oral dose of a drug one can compute the amounts suited for rectal and subcutaneous use by certain rules, but of course, no one denies that there are numerous exceptions to the rules given for the computations.

The following quotations, which might be multiplied almost indefinitely, illustrate what has just been said on this point:

Sollmann, "Text-book of Pharmacology," 1906, 2nd. ed., p. 134, states that "the rectal dose may approach very closely to the subcutaneous, especially with very active poisons. The hypodermic dose is about one-third of the oral dose."

Cushny, "Pharmacology and Therapeutics," 3rd. ed., 1903, p. 34, states: "*Hypodermic method.*—As a general rule about one-half of the ordinary amount is sufficient. *By rectum.*—The rate of absorption from the rectum as compared with that of the stomach and bowel is still a disputed point, and some physicians recommend that the dose be reduced to three-fourths, while others recommend one or one and a half times that given by the mouth."

The mere presence of a drug in the general circulation does not prove that the action is the same, quantitatively, irrespective of the way in which it was administered, but the physiologic action as a rule must be very nearly proportional to the amount present in the circulation at any one time, or in a unit of time.

Those drugs which are absorbed from the alimentary canal but which are destroyed in the liver before they reach the general circulation might as well remain unabsorbed, so far as their systemic action is concerned, and in our experiments such absorption has been disregarded, but no appreciable destruction of crystalline ouabain or amorphous strophanthin occurs in the liver of the cat or dog in the course of a few hours after the oral administration.

While the degree of dilution has a marked influence on the toxicity of certain poisons, such as strychnin, by

subcutaneous injection,² this must be regarded merely as a question of alteration of the ratio of absorption to excretion and destruction, for we have found that the slow intravenous injection of strychnin permits of the administration of several times as much as is fatal when the injection is made more rapidly.

We must suppose that the dilution of most drugs must be maximal after the oral administration, since the slow absorption from the stomach and intestine permits of the distribution throughout the body tissues. Mere dilution appears to play no important rôle in the action of the members of the digitalis group, particularly when these are very slowly injected, as in our experiments.

METHOD USED IN ESTIMATING ABSORPTION

We found that the absorption of a slight excess over the minimal fatal vein dose of crystalline ouabain, amorphous strophanthin, digitalis, strychnin and some other drugs into the general circulation was followed promptly by death, after typical symptoms, regardless of the way in which these drugs were administered, hence it remained merely to insure that the minimal fatal vein dose should enter the circulation. This was accomplished as follows: A measured amount of the drug to be examined was placed in the stomach, rectum or subcutaneous tissues, according to which structure was to be studied, and after the desired interval of time enough of the drug was injected intravenously to cause death. The fatal dose by intravenous injection being known, it was only necessary to subtract that required under the above conditions from the ordinary fatal dose by the vein, the difference being equal to that absorbed.

The following will illustrate the point: One part of crystalline ouabain injected into the femoral vein of the cat is fatal to ten millions of times its weight of animal, or, 0.1 mg. of crystalline ouabain is fatal to one kilogram of cat in this way. A cat received by the stomach 0.3 mg. ouabain per kilo of weight and after four hours it required 0.076 mg. per kilo to cause death. The difference between 0.1 mg. and 0.076 mg. being 0.024 mg., or 24 per cent. of the fatal dose by vein, it follows that the cat had absorbed an amount equal to 24 per cent. of the fatal vein dose, but only 8 per cent. of that administered by the stomach.³ The correctness of the method of estimating absorption is attested by the results obtained by the intravenous injections of variable proportions of the fatal dose of different digitalis bodies, death always resulting when the sum of the fractions administered equaled one hundred per cent. of the fatal dose. Fifty per cent. of the fatal dose of amorphous strophanthin by subcutaneous injection and fifty per cent. of the fatal dose of crystalline ouabain by the vein were also found to be fatal at once. We must conclude, therefore, that death follows the absorption of the fatal vein dose of one of the digitalis bodies into the general circulation, regardless of the method of administration.

This statement requires some modification. Since a barely fatal dose of crystalline ouabain might be absorbed slowly and a part excreted before the last had been absorbed without death occurring, it is more accurate to say that the presence in the general circulation of an amount equal to the fatal vein dose, is fatal to the animal.

2. Meltzer, S. J.: Jour. Exper. Med., 1901, v, 643.

3. The details of the method of injection are given in the Am. Jour. Pharm., 1910, lxxxi. The absorption of some of the digitalis bodies is estimated more conveniently, by substituting crystalline ouabain for the drug under examination for the intravenous injection, since we have found that these are capable of replacing each other in the proportion of their activity when injected by the vein.

1. Maurel's papers will be found in *Compt. rend. Soc. de biol.* during the past ten years.

In a series of experiments extending over several years we were able to get extraordinary uniform results with several of the digitalis bodies with intravenous injections into cats. Quite recently we have found a much larger number of cases in which the animal was more tolerant than just stated, but we have rarely seen animals succumb to smaller doses than that indicated except in the case of very fat animals. The results with strychnin are quite uniform when the duration of the injection is the same.

TABLE 1
ABSORPTION OF CRYSTALLINE OUABAIN FROM THE CAT'S ALIMENTARY CANAL

I.	0.3	2	10	10	30	After hydrated chloral.
J.	0.5	6	30	0	0	
K.	0.5	18	55	3	15	After hydrated chloral.
L.	0.5	18	35	0	0	
M.	0.8	19	35	4	30	
N.	0.8	19	35	0	0	After hydrated chloral.
O.	0.8	5	..	5	40	After hydrated chloral.
Dogs						
A.	0.2	6	30	0	0	
B.	0.2	3	40	12	100	After fasting 36 hours.
C.	0.5	3	0	2	50	
D.	0.6	6	40		10	

The question which presents itself naturally is why do we not determine the rate of absorption from the alimentary canal by the simple process of administering enough of the poison by the mouth to cause death? There are several objections to this apparently simple method in many cases. It has been found⁴ that the rate of absorption of strophanthin from the alimentary canal of the cat and dog depends on the amount administered, not only is a larger total amount of a very large dose absorbed than of a small dose, but a larger percentage of the larger dose is also absorbed. In fact, no absorption whatever appeared to follow moderately large doses in many cases, whereas death sometimes occurred promptly from large doses.

Another objection to the attempt to study the rate of absorption by the oral administration of the just fatal dose, depends on the fact that a very large number of experiments would be required to fix the just fatal dose by the mouth of such drugs as digitalis, and in fact it is

often impossible because of the frequency with which emesis follows the absorption of less than the fatal dose.

Table 1 gives the absorption from the cat's alimentary canal where the administration extended over a number of days. The variability in the percentage of the fatal vein dose actually in the circulation, as shown in the last column, is of especial significance in view of the fact that strophanthus, (as well as crystalline ouabain) is used clinically in doses which would be immediately fatal if administered by the vein.

The death of cat "A" affords a striking example of the rapidity with which absorption may occur, just as "L" and "N" illustrate the opposite extreme. Fasting and alcohol certainly appear to favor absorption, and this is true perhaps of other mild irritants, though it did not follow the use of mustard, small doses of which were ineffective while larger doses caused emesis. It should be observed that the figures after the decimal points in the dose are multiples of the lethal vein dose; thus cat "A" had twice the lethal vein dose, while "M," "N" and "O" had eight times the lethal dose by vein.

The fall of blood pressure caused by large doses of hydrated chloral may have some influence on absorption, but this is variable and uncertain. The results with dogs are only approximately accurate, the dose by vein required to cause death being variable.

TABLE 3
ABSORPTION OF STRYCHNIN FROM THE CAT'S ALIMENTARY CANAL

	Dose Mgs. Per Kg.	Duration		Per Cent. of Dose Ab- sorbed.	Per Cent. of Fatal Vein Dose Ab- sorbed.	
		Hrs.	Min.			
A.	0.35	..	28	..	100	Stomach full of meat.
B.	0.5	1	20	40	100	After fasting.
C.	0.5	..	..	..	..	Death occurred 33 minutes after rectal dose.
D.	0.25*	..	33	30	70	
E.	0.5	1	51	4	10	
F.	0.5	3	7	0	0	
G.	0.5	..	54	14	33	
H.	0.5*	1	28	30	70	
I.	0.33†	..	..	..	..	Equal to 1½ times fatal vein dose.

* Rectum.

† Subcut; animal survived.

Table 3 shows the amount of strychnin in the circulation after the expiration of the time indicated, rather than the actual amount absorbed, since excretion takes place rapidly, soon after its absorption, though it is stated that some days elapse before excretion is complete. Our experiments seem to indicate that the strychnin

leaves the circulation very promptly, a part of it being fixed in the tissues probably, or it may be that some of the strychnin administered by the stomach escapes absorption into the circulation.

In the table, "E" is given as having absorbed no strychnin, since it required the full fatal dose by vein to cause death. But the animal had a typical convulsion before the beginning of the intravenous injection, hence we must infer that excretion was equal to the amount absorbed from the alimentary canal. It is of the utmost interest that "A" died after 0.35 mg. by the stomach while that organ was full of meat, whereas "H" survived almost exactly that dose administered subcutaneously. Absorption of strychnin from the rectum appears to be more rapid as a rule than from the stomach.

TABLE 4

ABSORPTION OF DIGITALIS FROM THE CAT'S ALIMENTARY CANAL
BY STOMACH

	Dose Mgs. Per Kg.	—Duration—		Per Cent. Total Absorbed.	Per Cent. Fatal Vein Dose Absorbed.
		Hours.	Minutes.		
A.	100	3	26	16	16 Infusion.
B.	100	3	2	7	7 Infusion.
C.	100	3	9	34	30 Tincture.

BY RECTUM

D.	100	2	12	8	10 Tincture.
E.	100	4	37	2	2 Infusion.
F.	100	4	3	12	10 Infusion.

Table 4 shows the absorption of digitalis from the stomach and rectum. The limits of error are probably a little greater with digitalis than with crystalline ouabain. The fatal dose in the above table refers to the amount required by vein to kill at once, and is a little higher than the minimal lethal vein dose.

In this small series of experiments the absorption of digitalis from the rectum is decidedly less than from the stomach, but the number of experiments is entirely too limited to justify conclusions on this point. They certainly show the need of further studies in absorption of digitalis and these are now in progress in this laboratory. Different specimens of digitalis were used in the experiments tabulated, but in all cases the dose used was not far from the minimal lethal vein dose.

TABLE 5

ABSORPTION OF AMORPHOUS STROPHANTHIN FROM THE CAT'S
ALIMENTARY CANAL
BY STOMACH

	Dose Mgs. Per Kg.	—Duration—		Per Cent. Dose Absorbed.	Per Cent. Fatal Vein Dose Absorbed.
		Hours.	Minutes.		
A.	0.2	4	17	35	40
B.	0.2	4	55	12	15
C.	0.2	4	5	17	20

BY RECTUM

D.	0.2	4	1	15	17
E.	0.2	3	10	20	23
F.	0.2	4	26	0	0

Table 5 shows that the absorption of amorphous strophanthin is very irregular, varying from none from the rectum of "F" to 40 per cent. of the fatal vein dose in the case of "A," but even this series does not show as great irregularities in the absorption as we have found in previous experiments. The dose of amorphous strophanthin used in these experiments is but little above the minimal lethal vein dose.

SUMMARY

The absorption of many of the digitalis bodies and of strychnin from the alimentary canal of the cat into the general circulation is very variable. But strychnin may

be absorbed at times from the full stomach quite as rapidly as from the subcutaneous tissues.

Alcohol and perhaps other mild irritants favor the absorption of crystalline ouabain from the alimentary tract.

There is no general ratio of absorption of drugs from the stomach, rectum and subcutaneous tissues, and we are in urgent need of accurate observations of the rate of absorption of different drugs after various modes of administration.

There is a particularly urgent need for the investigation of the various digitalis bodies.

I am indebted to Dr. J. G. Brody for the care and patience with which he has carried out many of the experiments tabulated.

414 East Twenty-sixth Street.

STUDY OF SOME CASES OF ACUTE OTITIS
MEDIA, SEEN IN CONSULTATION*

HIRAM WOODS, M.D.

Professor Eye and Ear Diseases, University of Maryland
BALTIMORE

If the better class of general practitioners in Baltimore is typical of their associates in other cities, it is evident that appreciation of early ear troubles is keener than it was a few years ago. Physicians are learning that the welfare of the ear or, possibly, the issue of life and death, depends on the diagnostic acumen of the man who first sees the case. The lesson which specialists have been trying for so long to impress on general practitioners is being taken home at last.

During the past few years consultations regarding a possible otitic origin of systemic conditions have greatly increased. These consultations have developed a number of facts which, I have thought, might furnish a basis for profitable discourse: hence the presentation of so trite a subject as acute otitis media.

I. PRIMARY OTITIC INFECTION

The general belief in regard to otitis media, taught in text-books and unquestionably largely correct, is that the ear becomes involved as a sequel to infection elsewhere. Among these infections is that great waste-basket, grip. After a few days of fever, malaise, with no definite symptoms of anything, the patient, if a little child, puts the hand to the ear, thus calling attention to it, and examination reveals otitis media. Again, there is complaint of pain, followed in a few hours by discharge: or otorrhea is the first observed ear symptom. Diagnosis of grip, with secondary otitis media, is satisfactory to the physician, and, maybe, to the aurist, too. It was to me until the care of some medical friends in diagnosis taught me otherwise.

To justify the diagnosis of primary otitic infection we would have to find: first, systemic evidence of infection; second, objective evidence of ear disease; third, absence of all local or general disturbances capable of producing ear complications; fourth, relief of constitutional symptoms and restoration to health by treatment confined to ear drainage. Pain is such an overshadowing symptom of otitis as to be practically the only one of which the physician takes cognizance. But pain in a child, too young to tell about it, is easily overlooked. Another still more significant thing is that pain is by

* Read before the American Otological Society, at its Forty-third Annual Meeting, Washington, D. C., May 3 and 4, 1910.

no means invariably present in otitis media. Hence, if primary otitic infection is a reality, if it is capable of producing systemic infection, it is our duty to urge on the internist the necessity of including the ear in a routine examination for the cause of such symptoms.

The manner in which the infection reaches the ear without manifesting its presence elsewhere is interesting, and, possibly, not difficult of explanation. It is well known that infectious organisms of various kinds, virulent and innocent, stay in the nose and nasopharynx for a long time, producing no results. They could easily reach the tympanum and manifest themselves there. Again, it is conceivable that they could come through the circulation. The important clinical feature, however, is that this otitic infection does not always show itself in the orthodox order of exciting cause, pain, and other subjective symptoms before the discharge makes diagnosis certain. Without them, nothing but routine examination of the ear by a physician who has qualified himself to make it, can demonstrate the cause of general illness. If he appreciates the meaning of injection of malleus-handle vessels, redness of Shrapnell's membrane, or even knows that the ear can be primarily infected, and calls in a consultant, the diagnosis is easy. In a number of cases with such symptoms and objective evidence of otitis media, I have found slight impairment of hearing, lateralization by Weber's test, and have seen recovery follow incision of the membrane. In one case last year, that of a boy of 10, without pain, temperature of 104 F., and slight redness and bulging of the supero-posterior angle of the membrane, a single drop of streptococcus pus was evacuated, followed after a day by discharge. Symptoms were dispelled by the incision.

II. DELAYED APPEARANCE OF OTITIS

Akin to primary otitic infection are the delayed ear complications of various diseases. I allude to otitis media, sequel of infectious diseases, but removed from the causative disease long enough to throw doubt on causative relation. Either there is latent tympanic infection after the acute disease, or a new ear infection. For instance, a child has measles and passes through the attack without ear symptoms. Two or three weeks later, without other symptoms, and when recovery is seemingly complete, otitis media develops. Such cases, I believe, are not particularly uncommon, after measles and grip. In a few which I have seen there was the typical order of pain, fever and otorrhea, unless the case was seen before perforation. In others, sudden return of fever was the only symptom, and otitis was found because the physician looked for it or had it looked for.

Latent infection of the middle ear shows itself, too, in another way: apparent recovery of acute otitis media, with later mastoid symptoms. I brought this subject before the Section on Laryngology and Otology of the American Medical Association, in 1901, and have seen several cases since. One will suffice. A man of 48, after exposure in riding on the front seat of an electric car, developed pain in the right ear, with temperature of 102. He was seen by his physician, who found nothing but fever and ear pain. The drumhead presented all the indications for incision, but operation was refused. Two days later the physician reported that otorrhea had appeared, with relief of pain and fall of temperature. Soon I learned that hearing for the watch was normal and the patient entirely recovered. He went along with his business for seven weeks, when he was seized, while at his office, with severe earache. Mastoid symptoms developed rapidly, and on operation after

twenty-four hours the antrum and cells were found necrotic and full of pus. The easiest explanation seems to be that infection went to the mastoid at the first illness: but why it was so long in causing symptoms, or why the patient was apparently well for seven weeks, with disease progressing in the mastoid, is not so easy to explain.

Such cases have one important bearing on every-day otology. I believe that we all see cases of deafness following infectious diseases, without history or gross evidence of inflammatory otitis. There is nothing in the patient's condition to account for it. Fork tests show that it is due to middle ear disease. Inference seems justifiable that the acute disease left otitic infection not sufficiently virulent to cause immediate symptoms, but capable of doing one of two things: slowly breaking down tissue through spread of infection, or keeping up a constant hyperemia, leading to exudate, and so bringing about sclerotic changes in the tympanum. Among the facts we should try to impress on general practitioners are the following: that these latent ear infections are frequent; that their ultimate results are uncertain; that the tympanum is in the natural path of danger, just as the lungs are; and that the patient should not be dismissed as well until adequate ear-examinations have been made. In a few cases brought me by physicians after measles, scarlet fever, grip and the like, I have found interference with Eustachian function, and definite fork evidence of middle-ear deafness. Men should know from us that this is the time to save hearing.

III. PROLONGED REMITTING FEVER: DIAGNOSIS

A feature which often puzzles not only the physician but his consultant, is the meaning of prolonged fever in a seemingly light case of otitis media. During or after an infectious disease, otitis media develops. Maybe the membrane is incised; again it is allowed to ulcerate. The patient recovers from the original trouble, and to all appearances, from the ear complication. Pain disappears, the discharge lessens or ceases, hearing improves. Yet fever continues. If it is due to the ear it is our duty to get complete drainage: if not, the physician wants to know. It is a question of diagnosis which may, on the one hand, involve mastoid operation, not for mastoiditis but for tympanic drainage, and at the same time we must be careful not to operate on a patient for ear sepsis when he has something else.

Brief notes of three cases are appended.

CASE 1.—A man of 35 developed acute otitis media after rhinitis. Pus was found after membrane incision. Two days later, mastoid tenderness developed. Temperature for the first week is given in Figure 1. On the fourth day the patient was sent to the hospital, as mastoid operation was thought probable. Local symptoms were less pronounced the day after, and almost disappeared in another twenty-four hours. For the next three days the patient had a steady fever, without remissions. His physician, Dr. Charles W. Mitchell, was unable to determine its cause, if the ear and mastoid were excluded. Three factors in the case led me to exclude them: (1) steady improvement in local symptoms, and their total disappearance after a week; (2) character of the fever line; and (3) a leucocytosis of 4,000. Typhoid fever was thought of; but it was the sixteenth day before rose spots were found, and positive Widal was obtained only toward the close of the fourth week.

CASE 2.—This shows how easily a specialist can overlook a concurrent lesion. A healthy, athletic man of 29, without previous illness, was attacked early Saturday morning with a chill and right earache. He fought it out alone all day, but on Sunday called in an aurist, who found a temperature of 104 F., with objective evidence of acute suppurative otitis media. For

reasons I did not discover, he postponed incision until Monday afternoon when it was done at a hospital under chloroform. To Wednesday night temperature ranged about 102 without remission. Further operative procedures were then considered; but a consultation was asked by the family. I saw the case Thursday afternoon. That morning, six days after the initial chill, temperature had dropped to 97.5. I found the ear dry, and no evidence of mastoiditis. The outcome of the case was that the man was allowed to continue an uninterrupted recovery from an unrecognized, limited, right pneumonia.

CASE 3.—Temperature chart of a third case (Fig. 2) is given by way of comparison. The patient was a girl, aged 12, who developed left acute otitis media after apparent recovery from uncomplicated measles. She had been kept in the house and for the most part in bed for the eight days before ear trouble was found. Her physician, Dr. Mitchell, found it in routine examination for relapse of fever. She had nothing directing special attention to the ear. When called in, I found definite left suppurative otitis, without perforation, while the drum-head of the right was congested. Leucocyto-sis was 16,060. After left myringotomy, which I did at once, temperature fell from 104 to 101.6, and stayed there two days. Then the right drum-head was incised, though there was no pain. For the next five days there was remitting fever. On the fifth the left mastoid was tender to pressure, but no pain otherwise. I asked Dr. Harry Friedenwald to see the case with me, and we decided that symptoms were not sufficiently urgent for mastoidectomy,

of septic type, and profuse purulency. Chills, sweating, extreme variations in temperature (105 and upward, to subnormal), profound exhaustion—the things which lead us to uncover the sinus—are absent. The cases drag themselves along for weeks, with about such a temperature line as given in Case 3, without pain, and copious with purulent discharge. When they come to operation, extensive disease is found in the mastoid walls. A question I should like to hear discussed is: What is the line of demarcation between the safety of tympanic, and necessity for mastoid, drainage? Is there anything, outside of time and profuse discharge to guide us?

Fig. 2.—Temperature in double acute otitis media (Case 3), eight days after measles. First arrow point indicates incision of left membrane; second arrow point, incision of right membrane; third arrow point, second incision of left membrane.

Fig. 1.—Temperature in otitis media with typhoid fever (Case 1) in first week. Arrow point indicates incision of drumhead.

and that the left drumhead, the one first incised, which had healed, should be incised a second time. After this, mastoid tenderness disappeared, and recovery, though slow, was uninterrupted.

The case illustrates (1) the delay which may ensue after disappearance of the causative disease before ear complications develop; (2) what I believe to be the characteristic of otitic temperature—in all essentials, that of a mild sepsis; and (3) the value of leucocyte count. When able, I have this count made in acute otitis media, and it rarely is below 15,000. Considerable observation of cases like these has led me to think that in the temperature line and leucocyte count we have pretty reliable guides regarding an otitic cause of systemic disturbances as distinguished from essential fevers. There is always the possibility of another lesion with the ear trouble.

There is another side to this matter. Sometimes we are compelled to do a mastoidectomy for drainage, though there are no symptoms of mastoiditis. Even when the process is painful on pressure, tympanic drainage is often enough. In deciding if mastoid drainage is needed I believe that the amount of the otorrhea is an important guide. There is nothing new about this, yet it is a guide often neglected. It is unnecessary to relate cases in which, without definite mastoid symptoms, operation has been done because of persistent fever,

IV. CONVULSIONS

I want, finally, to call attention to three cases of acute otitis media, which were new observations to me.

CASE 4.—The first case is that of an infant, 5 months old, whom I saw in consultation with Dr. Thomas R. Brown. At the age of 3 months the baby had measles, which left in its wake enlarged cervical glands. The week before I saw her, she had a transient, general vesicular eruption which Dr. Brown diagnosed as chicken-pox. Three days after the disappearance of the eruption, there was a convulsion, followed by stupor, lasting an hour or so. Rectal temperature was 103. Dr. Brown found a leucocyto-sis of 18,000 at his first visit. While he was in the house the child had a convulsion, with dilated

Fig. 3.—Temperature in otitis media, with referred pain (Case 6). Arrow point indicates myringotomy for scalp pain.

pupils, rigidity and unconsciousness. Dr. Brown examined the ear, and found, as he thought, redness and bulging of the supero-posterior angle of the membrane. I was called in at night. Temperature then was barely 100; the child was free from pain, took its bottle eagerly, and did not look sick. The right drumhead presented evidences of otitis media; but there was no bulging, and in view of the generally improved condition, I decided to do nothing till the next morning. At 8:45 a. m. I received a telephone message that the child was worse, had had two convulsions, and rectal temperature was 103. As soon as possible Dr. Brown and I reached the country home

of the patient's parents. The drumhead was now bulging in the supero-posterior angle, and leucocyte count was 24,000. Without anesthetic I incised the drumhead, continuing the incision into the canal wall. A very little pus was evacuated, and recovery was uneventful. At no time was there evidence of pain.

While this is my one observation of ear convulsions, I have known, as have all of us, of babies dying of supposed meningitis, with otorrhea toward the close. I can count a half dozen such cases in the families of friends, and learned of in conversation with physicians. The intimate connection between the tympanic and cranial cavities in infancy, through the squamo-petrosal suture, is probably sufficient explanation. The interesting fact, however, is that physicians are appreciating such possibilities.

V. REFERRED PAIN

The other two cases I have classified as "referred pain."

CASE 5.—The patient was a nurse, aged 24, at the Union Protestant Infirmary, who came to me on January 25 last for diagnosis. Two nights before I saw her she was awakened by severe pain along the anterior border of the sternocleidomastoid muscle, at least two inches below the tip. The slightest pressure here over an area of an inch in circumference was painful. Temperature was normal and no hearing defect could be found. The drumhead presented a normal appearance. Leucocyte count was 8,000. The patient was put to bed and given first salicylate of sodium, and later acetylsalicylic acid (aspirin), with little effect. Morphine was needed to secure relief from the strictly localized pain. The only pain in the ear proper was produced by brushing the posterior wall of the canal with a cotton pencil or touching it with a probe. Hearing for the watch gradually diminished, and in four days was only on contact. A loud whisper could then be heard at two or three feet, and fork test, Weber's, was lateralized to the bad ear. I could find nothing by inspection, save, possibly, increased blanching of the drumhead. Temperature during these five days did not go above 99.5. On January 31, on account of the falling off in hearing, I determined to incise the drumhead, which was done under nitrous oxid. The membrane cut like stiff parchment. Through the lips of the incision there escaped a few thin flakes looking like very thin bits of paper. They were lost in a drop of clear fluid which followed them and the little blood from the upper edge of the incision. The next day the patient heard the watch at 6 inches, and in a short time had normal hearing. Twice after incision, on February 1 and 2, temperature reached 101. This followed an attempt to syringe the little clot from the canal. The pain in the muscle was relieved at once by the incision of the membrane.

CASE 6.—Dr. Brown asked me to see with him Mr. W., a lawyer, aged 49, who had been first seen by Dr. Brown on the morning of March 21 for a slight right tonsillitis. It subsided after two days. Dr. Brown was summoned again early in the morning of the 24th for severe pain in the right parieto-occipital region. As seen by the chart (Fig. 3), there was a temperature of 101.6. I saw Mr. W. on the morning of the 25th. A mustard plaster had been applied, before Dr. Brown's visit, and the scalp was reddened. Pain came in paroxysms, the slightest movement producing it. It was confined to a limited area, at least 2 inches behind the meatus, the intervening space over the mastoid being free from tenderness or congestion. The drumhead presented the appearance of a mild catarrhal otitis. Hearing was normal for watch and speech. Because of the remoteness of pain from the ear, and normal hearing, I hesitated to connect the ear with the occipital pain. The patient was given an atropin and cocain solution to use during the day, but reported in the evening that he had had no relief. His temperature was 102, while the drumhead presented the same appearance as in the morning. Weber's fork test was lateralized on the affected side. In spite of morphine the patient had a wretched night, every movement of the head causing paroxysmal pains limited to this one spot in the scalp.

I saw him again at 8 a. m. on the 26th. He was prostrated by two sleepless nights, and accepted what I told him was a purely experimental incision of the reddened supero-posterior angle of the drumhead. His hearing was absolutely unaffected save for Weber's lateralization. Fair anesthesia was obtained by an alcoholic and oily solution of cocain (20 per cent.). Relief from pain was almost magical. As in the case of the nurse, the drumhead cut "stiff." There was some little hemorrhage, but no pus, so far as we could see. Recovery was prompt without impairment of hearing.

I presume that these referred pains were due to an unusual connection between the tympanic nerve and other branches of the glossopharyngeal through the petrosal ganglion.

I have thought these observations in acute otitis media of sufficient interest to put on record. Behind them, however, is the fact that but for the thoroughness of diagnosis on part of the internist, the cause of the fever, convulsions, pain would not have been determined. Improved attitude toward ear troubles on part of our medical associates has brought about a definite change in our practices; at least, in mine. In private work chronic suppurative otitis media, of which years ago I saw so much, is rare. Even acute otitis media, allowed to go on to ulceration of the membrane is not very frequent. But constitutional symptoms due to ear disease, without gross evidences of the latter, are more common. The moral of it all is that aurists must be good enough physicians to make differential diagnoses.

842 Park Avenue.

THE CLOSE RELATION OF THE DENTIST TO THE PHYSICIAN*

B. E. BUSH, M.D.
CHICAGO

More intimate cooperation between dentist and physician would be beneficial alike to the patient and to the profession. Dentistry is a specialty of medicine; the stomatologist, with a broad knowledge of general medicine and a particular training in his own field, is exactly on a par with the oculist, the laryngologist or the obstetrician. Thorough knowledge of the principles of medicine must underlie all successful treatment of disease, and the patient must be regarded as an individual, not a collection of separate organs, each to be treated alone. Since one region of the body cannot be isolated from the entire organism or separated in its development, nutrition, function or diseases, neither can its treatment be a separate matter. The person attempting to treat one part of the system must understand the whole, at least broadly, in order to apply general pathology and therapeutics to his particular part. With this intelligent survey of the whole field, the dentist can be a most efficient factor in the prevention of disease and in its successful treatment. A fuller appreciation of their mutual interests would bring the family physician and dentist more often together in their work.

Many cases of general asthenia, malnutrition and anemia under medical treatment are primarily due to oral causes; and not all the tonics in the Pharmacopeia will suffice to cure the patient who cannot chew his food, or who is constantly swallowing bacteria and their products from conditions of oral sepsis, such as dental caries and pyorrhea. In daily practice these unfortunate patients are a trial to their physician, who seldom

* Read in the Section on Stomatology of the American Medical Association, at the Sixty-first Annual Session, at St. Louis, June, 1910.

accomplishes much toward permanently relieving their state of health until he examines the source and not the sequel of the symptoms, and insists on proper treatment of the mouth and teeth. The careless doctor, who hastily writes a prescription for pepsin for the dyspepsia, cascara for the constipation, or iron for the evident anemia in such a case, will be disappointed in the results of his treatment unless he goes much farther and seeks and removes the cause of the trouble. Consultation with an able dentist will often save the patient great expense and much depreciation in health, and prove the real way to recovery; whereas months of desultory medical treatment alone would bring only trifling and temporary improvement of symptoms—to the disgust alike of the patient and physician, who often part company at this stage with a feeling of mutual relief. The busy physician dismisses the matter from his mind with the thought that “there’s no satisfaction in treating these chronic cases that are all run down,” while the patient either plods along on a lower level of efficiency than he should be occupying, or suffers still further from the natural development of his morbid state. After a time secondary conditions arise. Chronic nervous and mental disturbances may appear, neuralgia, insomnia and the various fatigue neuroses, leading, in neglected cases, even to a complete physical and mental breakdown.

A fair review of these cases shows that the terminal symptom-complex was rendered possible by the low vitality of the patients, that is, by anemia and malnutrition, due to a chronic indigestion caused by imperfect mastication due to faulty teeth. Therefore, the logical early treatment was dental rather than medical; and the family physician should have pointed this out. Among his many mistakes, the sins of omission are not the least important.

Still more is this true in the case of children, in whom neglect of proper dental treatment leads often to defects of growth that become irremediable. Living proofs of this are to be seen on every hand, but even yet are not receiving the attention they merit. Take for example, the numerous cases of nasal obstruction, with adenoids, enlarged tonsils, and often recurring catarrhal inflammation with or without extension to the frontal and maxillary sinuses, or the Eustachian canal and middle ear or mastoid cells. How many physicians or general surgeons realize the advantage of cooperation with the dental surgeon in the treatment of these children? It is not enough to tell the parent to have the child’s teeth attended to and his tonsils and adenoids removed. In too many instances this does not end the trouble. The narrow arch and nostrils and high palatal vault with deflected septum will maintain the habit of mouth-breathing; the pharynx and mouth will be dry and irritated; the larynx, trachea and bronchial tubes will be injured by the rapid inhalation of unwarmed, unfiltered air, and danger to the lungs may ensue. As the child attempts to overcome his mouth-breathing habit, he is obliged to breathe more slowly and less deeply than normally through his nose, and suffers from the diminished supply of oxygen. His impeded respiration requires an increased action of the voluntary respiratory muscles and leads to faulty growth of the chest wall resulting in protruding sternum and scapulae, high shoulders and spinal distortion, while his whole respiratory condition impairs his vitality and favors the onset of disease, colds, catarrhs, deafness, mastoid disease, quinsy, tonsillitis, rheumatism, diphtheria, scarlet fever and tuberculosis. And this is not all. The child of

this type has a narrow arch, too small to accommodate his permanent teeth. As these are erupted, the crowded teeth may give rise to much prolonged pain and nervous disturbance which the undervitalized child is ill able to bear. With his irregular teeth he cannot masticate his food properly, and again his nutrition suffers. Deprived of abundant oxygen and digestible food-supply, he becomes the easy prey of the diseases of adolescence. The remedy is plain, namely, proper combined dental, surgical and medical treatment early in the case, and continued long enough to correct the deformity.

The surgeon and the dentist may well work together in the treatment of fractures of the jaws, in which the dentist can make a splint for retaining the fragments in position until bony union occurs, much more satisfactory than the one the surgeon is likely to buy or devise for himself. Even in the surgery of the cranial vault, a closer association of surgeon and dentist would benefit the patient, the dentist’s familiarity with the dental engine enabling him to cut with delicacy and precision in places where the ordinary trephine or chisel would be most unsatisfactory and hazardous. So also with the drilling of holes for nailing or wiring bony fragments in fractures of the long bones, the drill operated by the dental engine being far superior to any hand drill or to the hammer and nail which too often splinter the bone. In some orthopedic work, the dentist, with his greater knowledge of mechanics and skill in the use of metals, could often help much in the adjustment of splints and appliances.

In various suppurations about the head and neck, the surgeon is often at a disadvantage without consultation with his dental confrère. Antral disease of nasal or dental origin, parotid or submaxillary abscesses, swollen or suppurating cervical lymph glands, periostitis or necrosis of the maxillae may be due, more or less directly, to faulty dental conditions—a fact which the surgeon is apt to overlook, but which is readily apparent to the dentist. The more obscure cases of neuralgia (so-called) will sometimes require the united efforts of dentist and physician to illuminate their etiology and direct their successful treatment.

Another line in which the physician and the dentist may help each other is the giving of anesthetics. Few general surgeons are fully acquainted with the many advantages of nitrous oxid and not only omit to use it when operating themselves, but advise patients not to take it, even for dental operations. Such advice must result from a meager knowledge of its effects, and cannot be other than detrimental to the patient’s interests in many operations in which anesthesia is required for but a short time. For prolonged operative work the combined use of nitrous oxid and oxygen gives a satisfactory anesthesia in most patients, especially in those with chronic bronchitis, valvular heart disease or some other contra-indications for either chloroform or ether. The ease and rapidity with which the patient is put to sleep, the safety with which that sleep may be prolonged by giving oxygen with the nitrous oxid and the quick awakening to consciousness, usually without nausea, render this method of anesthesia an ideal one for many dental and surgical operations, although there are certain drawbacks to its use. It is more expensive than chloroform or ether, less readily obtained away from large cities, less easily kept on hand for emergencies and less easily carried and handled, outside of the office or hospital. On account of his better training and wider experience with this anesthetic, the dentist may properly be called on to administer it for surgical oper-

ations, just as the physician is asked to give ether or chloroform for dental operations. In any operation requiring a general anesthetic, neither surgeon nor dentist should be willing to operate without the assistance of a competent anesthetizer who can take full responsibility for the patient's condition.

In conclusion, the interests of the patient would be furthered by consultation between the physician and the dentist, not only in occasional operations and in special cases of injury and deformity, but in many conditions of acute and chronic disease. An intelligent acquaintance with each other's work and a friendly understanding of mutual respect between the members of the profession is greatly to be desired.

1644 Morse Avenue.

ABSTRACT OF DISCUSSION

DR. LEE WALLACE DEAN, Iowa City, Iowa: No physician should ever remove in a child nasal or postnasal obstructions without sending that child to the dentist; if he does so he does an injury to his patient. The teeth I know but little about, but I do know that they may look all right to the physician when they may be too close, or there may be other conditions which will cause that child trouble in years to come. I do know that practically every child that has adenoids or postnasal obstruction removed has some irregularity or disturbance of the teeth. In my clinic I find there are few cases of postnasal obstruction in which there is not some disturbance that the students can detect. Every one of these children coming into my hands is sent to the dentist. I regret to say that the great majority of them do not get to the dentist; I have done my duty. No rhinologist is ever justified in removing turbinate tissue from a nose to secure breathing-space, so long as there is a chance for that breathing-space to be secured by the dentist.

It seems to me that the dentist should refer cases to the rhinologist. All patients with irregularities of the teeth should be examined for nasal and postnasal obstruction. Many cases of caries of the teeth might be influenced by mouth-breathing at night, and the dentist might be wise if he would send these patients to the rhinologist to see if there was a condition that might result in mouth-breathing at night.

THE SYMPTOMATOLOGY AND DIAGNOSIS OF MENINGITIS OF OTITIC ORIGIN*

EDWARD BRADFORD DENCH, M.D.
NEW YORK

This subject has been so thoroughly discussed during the past few years that it would seem presumptuous for me to attempt to add any new facts. I can only hope, therefore, to present the matter in the manner in which it has been brought to my attention from the observation of a rather large number of cases.

We may classify meningitis of otitic origin as (1) circumscribed meningitis or epidural abscess, (2) serous meningitis, and, (3) purulent meningitis.

Of the symptomatology of circumscribed meningitis, very little need be said. In most cases, the diagnosis of this condition is made on the operating table. A circumscribed pachymeningitis is an effort on the part of nature to prevent general infection of the subdural lymph sac; in other words, to prevent a diffuse, purulent meningitis. The only symptoms which these patients present are localized headache in the region of the puru-

lent collection, and a slight elevation of temperature. These symptoms, occurring in the course of an acute otitis media, whether or not they be complicated by evidences of mastoid involvement, are sufficient to warrant the surgeon in suspecting incipient meningeal involvement. In quite a large proportion of my own cases, I have been able, from these symptoms alone, to make a diagnosis of a localized pachymeningitis. As before stated, however, a localized collection of pus, lying between the dura and the bone, is frequently found at the time of operation on the mastoid, without any suspicion of its existence, on the part of the surgeon prior to the time of operation. While these cases are frequently not considered under the head of "otitic meningitis," on account of the extremely indefinite symptoms which are presented, it seems to me that they deserve more than passing attention. Given a case of acute inflammation of the middle ear or of a chronic inflammation of the middle ear, with an acute exacerbation, in which the patient complains of localized headache, rather than of severe pain in the ear or pain in the mastoid, and localized tenderness either in the post-mastoid region or just above the zygoma, we are, I believe, warranted in suspecting that the inflammatory process has extended beyond the limits of the mastoid, and that it has already involved either the cerebellar fossa or the middle cranial fossa.

Aside from these symptoms of moderate temperature elevation and localized headache, together with local tenderness, I know of no means of making a diagnosis of this condition. But, given these symptoms, I believe that it is always wise for the operator in exploring the mastoid, to consider seriously the exposure of the dura in the middle cranial or cerebellar fossæ, as a final step of the operation.

THE SEROUS AND PURULENT FORMS

The second and third division of the subject are of much greater interest—that is, cases of serous meningitis or diffuse purulent meningitis, following inflammations of the middle ear. Whether the inflammation of the cerebral membranes is serous or purulent depends very largely on the virulence of the infecting organism. It is probable that a serous meningitis is invariably present in the early stages of a purulent meningitis. If the resistance of the patient is sufficient to combat successfully the constitutional infection, the subdural effusion remains serous. If, on the other hand, the infection is severe, the subdural space is invaded by the micro-organism and a purulent meningitis is the result.

We know from post-mortem examinations that the most frequent avenue for the transmission of infectious material from the middle ear to the meninges is through the labyrinth, either directly through the internal auditory meatus, or through the aqueductus vestibuli or aqueductus cochleæ.

Lermoyez,¹ in his admirable article, says that in 65 per cent. of all cases of otitic meningitis, the invasion takes place through the internal ear. In the remaining cases, the infection of the cerebral membranes takes place by continuity of structure, either in the middle cranial fossa, or in the cerebellar fossa, either directly or through the lateral sinus.

DIAGNOSIS

In cases of suspected meningitis of otitic origin, therefore, an early investigation should always be made for evidences of labyrinthine involvement. The patient should

* Read in the Section on Laryngology and Otology of the American Medical Association at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Tr. Eighth Internat. Otol. Cong., Budapest, p. 4.

be carefully examined for any disturbance of equilibrium, such as a staggering gait when walking with the eyes closed. This examination can be made only in the very early stages of the disease. The eyes should also be examined for nystagmus. In the early stages of a labyrinthine involvement, this nystagmus may occur either toward the affected side or toward the healthy side. As the labyrinthine lesion progresses, however, the nystagmus toward the affected side disappears and the nystagmus toward the healthy side becomes marked, this symptom being an evidence that the affected labyrinth is paralyzed. An investigation of the labyrinth should, when possible, be made, both by the turning test and by the caloric test, in order to determine the exact condition of the labyrinth, and to discover the true significance of the nystagmus. It should also be remembered, in cases of meningitis involving the vestibular nerve, that a nystagmus toward the sound side, indicating a paralysis of the affected labyrinth, may later disappear and a nystagmus toward the affected side make its appearance. This is positive evidence of a retrolabyrinthine lesion—that is, of a lesion either in the cerebellar substance or in the meninges in the immediate vicinity of the vestibular nerve.

In cases of otitic meningitis, in adults, an examination of the hearing is of considerable importance. It is hardly possible to have the vestibule involved, to any extent, without having considerable involvement of the cochlea. For this reason, the appearance of sudden and profound deafness in a case of middle-ear suppuration, particularly if associated with vestibular symptoms—should always lead the surgeon to suspect a beginning meningitis.

Involvement of the cochlea ordinarily manifests itself: first, by profound deafness, second, by loss of bone conduction, and third, in the failure of perception of the high notes of the musical scale. As invasion of the cochlea in these cases ordinarily occurs directly from the middle ear, it is easily understood why this perception of the highest tones of the musical scale should be lost, since that portion of the cochlea nearest the tympanum is concerned in the perception of these high notes.

Many authors speak of the occurrence of facial paralysis as a symptom of considerable importance, and one which should lead the observer to fear a beginning meningitis. While at first this seems plausible, it has not been borne out in my clinical experience. For instance, I have seen a large number of cases of facial paralysis occurring in the course of middle-ear suppuration, in which the patient never exhibited the slightest evidence of meningitis. Many of these cases have been followed for a long period of time, so that, had any meningeal symptoms developed, they would certainly have been recognized. Naturally, I am here referring to the cases of facial paralysis occurring in the course of the suppuration, and not to those dependent on traumatism at the time of operation.

It is probable that a serous meningitis is almost never fatal. In my experience, I can remember but one case in which, though the cerebrospinal fluid remained sterile, a fatal outcome followed. It is likely that in the first stage of every meningeal inflammation, we have a serous effusion in the subdural space, and, in some cases, into the lateral ventricles as well. If these spaces become invaded by the specific microorganisms, then a purulent meningitis follows. If, however, such infection does not take place, the serous effusion is gradually absorbed and recovery occurs.

Certain surgical and therapeutic measures are unquestionably of value in this serous stage, and these will receive proper attention at the hands of my distinguished colleague, Dr. Mygind, who is to speak on the treatment of otitic meningitis. As the symptoms of the serous form of meningitis pass, with almost imperceptible gradations, into those of the purulent form, I shall not attempt to make any distinction in the symptomatology.

COURSE

The course which a purulent meningitis may run, may be divided into two types:

1. The rapid or fulminating type.
2. The slow or progressive type.

In the fulminating type of meningitis we have very few symptoms. The disease runs its course with great rapidity, and may cause death within a few hours.

CASE.—In a case observed some time ago, the patient, a child of about 4 years, had suffered from a double acute otitis media for about ten days before I saw it. At the time the patient was first seen, both ears were discharging slightly, a myringotomy having been previously performed on both sides. Both drum membranes were at once freely incised, this procedure being followed by a fall in temperature and a more profuse discharge. The patient up to this time had exhibited no cerebral symptoms, although there had been an elevation of temperature from 102 to 104. Three days after I first saw the patient the temperature suddenly rose to 105.5, and both mastoids were opened. A considerable amount of softened bone was found on each side. Owing to the sudden, abrupt rise in temperature, both lateral sinuses were exposed, as it was thought possible that there might be a thrombosis of the lateral sinuses. Both sinuses were found normal, and, consequently, were not opened. The child rallied immediately after the operation, but twelve hours later the temperature began to rise slowly, the pulse became poor and rapid, the child gradually sank into unconsciousness, and died in about thirty-six hours after the operation. The infection, in this case, was a pneumococcus, and, although no autopsy was permitted, the diagnosis of a pneumococcus meningitis was made.

I have seen cases of this kind occasionally, and they certainly present a distinct type of the disease.

SYMPTOMS AND DIAGNOSIS OF PROGRESSIVE MENINGITIS

When we come to the consideration of the slow or progressive type of meningitis, we have certain symptoms which aid us in our diagnosis. In adults, in the severe cases, headache is a prominent symptom. This is usually severe in character, and is general rather than localized. Vomiting also occurs in a large proportion of cases, and this vomiting is ordinarily preceded by constipation. The temperature is a valuable indication. In the severe cases the temperature is ordinarily considerably elevated, rising quickly to 104 or 105, and seldom dropping more than a degree or a degree and a half below this level. In the milder cases of meningitis—that is, probably, during the serous stage of the inflammation—the temperature may not be so much elevated. I have seen a number of cases in infants run their entire course and terminate fatally without the rectal temperature rising above 103 until just before death. It has been my experience that the cases in adults run a very much higher temperature than do the cases in infants, this being exactly the reverse of what would be expected. It has also been my experience that vomiting is a rather more common symptom in adults than in infants.

NEUROMUSCULAR SYMPTOMS

Localized neuromuscular symptoms may appear early in the course of the disease, and this applies both to the serous and purulent varieties. These neuromuscular

symptoms affect usually the ocular muscles. In the early stage of the disease, we ordinarily have a contraction of the pupil on the affected side, and not infrequently have a paralysis of the sixth nerve on the corresponding side, leading to an internal strabismus. As the disease progresses, the contraction of the pupil disappears, and, owing to a partial paralysis of the third nerve the pupil becomes gradually dilated. While the paralysis of the sixth nerve is ordinarily confined to the side of the affected ear, I have seen an abducens paralysis of the opposite side. This, of course, is easily explained from the fact that the apices of the petrous pyramids lie in close proximity, and a meningeal inflammation may easily extend across the median line, and involve the abducens of the opposite side, although the abducens of the affected side may escape.

Stiffness of the neck is one of the earliest neuromuscular symptoms met. This ordinarily occurs both in children and in adults, in the very early stages of the disease. In infants, I look on rigidity of the neck as one of the earliest symptoms of a meningitis, especially if this sign is associated with an elevation of temperature.

REFLEXES

The patellar reflexes are usually increased, the exaggeration being more marked usually on the affected side, in the early stages. The Kernig sign is usually present, and in a number of cases I have been able to elicit the Babinski sign early in the course of the disease.

MENTAL CONDITION

In adults, the mental condition of the patient is of considerable significance. In the early stages, there is frequently a mild delirium, this condition passing into coma as the disease advances. In children, instead of delirium, we may have general convulsions, although, in my experience the occurrence of convulsive seizures is rather rare in an otitic meningitis.

THE BLOOD

The examination of the blood is sometimes of value. In cases in which a differential blood-count has been made, I have usually found a high leucocytosis, and a decided increase in the polymorphonuclear percentage. In most of the cases the polymorphonuclear proportion has been between 85 per cent. and 90 per cent. Whenever, as the result of therapeutic or operative measures, a temporary improvement has taken place, this has always been followed by a fall in the polymorphonuclear percentage. It seems, therefore, that the differential blood-count, in these cases, is a valuable aid in diagnosis.

THE CEREBROSPINAL FLUID

The most certain and convincing evidence which we have of the presence of a meningeal inflammation is the information derived from a lumbar puncture. This puncture should always be made early in doubtful cases, and may be repeated as frequently as is necessary. In most instances, the cerebrospinal fluid will be found to be under considerable tension. In cases in which there is a great increase in the amount of the cerebrospinal fluid, on lumbar puncture it will be forcibly expelled from the exploring needle. I have seen the jet rise several inches above the opening in the needle, with the patient in the prone position. The physical character of the cerebrospinal fluid is naturally an aid to diagnosis. If there is a clear fluid which, on microscopic examination shows no micro-organisms and few or no leucocytes,

we have to deal with a serous meningitis. If, however, the fluid is cloudy or turbid, and contains a large number of broken-down leucocytes, particularly of the polymorphonuclear variety, and also contains micro-organisms, we have to deal with a purulent meningitis. It should be remembered that an increased amount of serous fluid in the spinal canal may not, of necessity, mean an inflammation of the cerebral membranes. Such an increase in the cerebrospinal fluid is found in cases of neoplasm within the cranial cavity, and in cases in which the cerebrospinal fluid is germ-free, and contains no pus-cells, the possibility of an intracranial neoplasm should always be borne in mind.

The character, then of the cerebrospinal fluid is, perhaps, the most important element in diagnosis. If we have to deal with a fluid free from germs and containing no pus, we know that we are dealing with a meningitis in its early stages. It is probable that in cases of this character simple relief of pressure and a thorough eradication of the focus of infection will be sufficient to effect a cure. In cases in which the cerebrospinal fluid contains one of the various micro-organisms so frequently found, such as a pneumococcus, streptococcus or meningococcus (*diplococcus intracellularis*), very radical surgical measures must be taken in order to give any hope of relief.

OCULAR SYMPTOMS

An examination of the fundus oculi will, in many cases, show the presence either of beginning or of well-marked choked disc. These changes in the optic nerve are common to all cerebral lesions, accompanied by an increased intracranial pressure. While, therefore, the swelling of the optic papilla with dilatation and tortuosity of the veins cannot be regarded as in evidence of meningitis, but simply as a sign of some intracranial complication, the occurrence of this symptom, in connection with the other symptoms already mentioned, will, of course, be a valuable aid in confirming the diagnosis. The ocular changes may occur on either side, but are most commonly found on the side corresponding to the ear involved.

CONCLUSION

I regret that I have been able to add so little to the knowledge of the subject at hand. I have simply stated the results of clinical experience. It has appeared to me in the course of my observation of cases of meningitis, that the earlier we can make the diagnosis, the better will be the prognosis. In other words, if the symptoms of meningitis are recognized early, the surgeon by prompt interference may be able to prevent the disease from passing beyond the serous stage, and, in some cases, in which an actual infection of the subdural space has occurred, may be able promptly to remove the source of infection and to effect a cure. The longer the duration of the case, however, the more grave the prognosis. Therefore, as stated above, my own observations have led me to believe that the cure of an otitic meningitis depends on its early recognition.

"Piano-Key" Dislocation of the Outer End of the Clavicle.—An illustrated study of this condition is published by F. Dominguez in the *Revista de Med. y Cirugia*, 1910, xv, 333. It is based on three cases from his personal experience, the only ones of the kind he has ever encountered and all within three months. A wire suture is required to hold the end of the clavicle permanently in place.

THE INDICATIONS FOR SURGICAL INTER-
FERENCE FOR THE RELIEF OF
OTITIC MENINGITIS *S. MACCUEN SMITH, M.D.
PHILADELPHIA

On account of the apparently increasing prevalence of otitic meningitis, especially in children, due, no doubt to our greater ability to recognize the disease, the subject is of the utmost importance, not only to the aurist, but more especially to the physician of general practice, since he is usually the first to be consulted in the initial illness. The questions pre-eminent, therefore, for our consideration are (1) the establishment of a prompt diagnosis of otitic meningitis, still replete with difficulties; and (2) the adoption of immediate measures for its relief, an accomplishment even more perplexing than the first.

As all scientific attainment, however, is developed by slowly progressive steps, judging from the progress of the recent past, we have every reason to feel encouraged in the belief that, in the very near future, we shall have reached the goal whereby our ability to diagnose this disease promptly will be unfailing, and furthermore, the technic of surgical intervention will have become so thoroughly mastered that a favorable prognosis may be the rule, instead of the exception, as to-day. The optimistic picture here drawn for the future seems almost heresy in contrast to the pessimism manifested by the profession in the past, or even at the present time, and yet I must be insistent in asserting the belief that this outlook is only as bright as the expectant and progressive future has every right to expect, especially if the original work of Jansen, Neumann and others is to be emulated by our colleagues.

Please note the emphasis and importance I wish to place on the words "prompt" and "immediate" in their connection with the diagnosis and treatment of otitic meningitis, for, without proper appreciation of their application in this disease, the ravages of the past on human life must be perpetuated indefinitely. In consequence of the present demand, we now yield to the collective opinion that our only means of successful intervention lies in operative interference, and I will endeavor to mention the various surgical procedures incident thereto, in compliance with my obligation to this part of the symposium assigned me.

On account of the symptom-complex which so frequently confronts us, and our consequent inability to differentiate between meningitis and encephalitis, I must agree with Körner (and this is confirmed by my limited post-mortem opportunities) that the actual condition is best characterized by the term "meningo-encephalitis" instead of the word "meningitis," and surely this does not overstate its gravity in the more severe type of this disease.

If we accept the theory that serous meningitis, as demonstrated by Quincke's lumbar puncture, is simply an increase in the amount of cerebrospinal fluid; we have a plausible explanation of the fact that in so many cases of this particular type the patients recover, when the condition is properly diagnosed and the fluid drained surgically. Furthermore, if we agree that serous meningitis is the first stage of the suppurative form, it being most difficult to determine where one ends and the other

begins, we have additional reason for an early lumbar puncture, which must be followed promptly by more thorough drainage, if the symptoms are not relieved by the former.

Some serous cases presenting typical meningeal symptoms with a normal fluid under high pressure have also a circumscribed purulent leptomeningitis, the toxins giving rise to an increased cerebrospinal pressure, but not altering the fluid's physiologic consistency; here the indications for thorough drainage by operative measures are manifest. In our eagerness to relieve serous meningitis by surgical intervention we must not lose sight of the well-recognized fact that many patients will recover by lumbar puncture and removal of the focus of an aural suppuration and exposure of the dura. Exploratory operations on the brain, therefore, should be deferred until the results of the former are observed.

Much divergence of opinion exists as to the curability of a general suppurative meningitis; the subject, however, is governed largely by the individual conception of the terms "general" or "diffuse." On this subject Heine¹ says:

I agree with Lexer that the words "circumscribed" and "diffuse" have been differently understood by different authors. In discussing inflammation in serous membranes Lexer distinguishes three forms, the encapsulated, the acutely progressive and the general. In the encapsulated form the opposing serous surfaces are firmly bound together around the area of inflammation by fibrinous exudate and granulations. In the progressive form either the tissues fail to effect this shutting off of the focus of inflammation or the infection, at first confined, breaks through the protecting wall and spreads rapidly. Finally, the general form, in which the whole serous lining of the cavity is involved, is a further development of the progressive variety. These different forms are best seen in suppurative peritonitis, of which the acute progressive stage may be checked sometimes by operation, but the generalized form is always fatal.

Heine is of the opinion that "the circumscribed and progressive forms of suppurative meningitis are curable, but the prognosis in the generalized form is absolutely unfavorable."

Judging from the above classification it may be that some of us have accepted as identical the diffuse and progressive forms of suppurative meningitis, in which event we can readily account for the reported recoveries. I am of the opinion that generalized suppurative meningitis is incurable by any therapeutic measure at our present command; this, however, should not deter us from adopting prompt surgical intervention, from the fact that we are not yet competent to determine unqualifiedly the exact stage to which an advanced case has progressed. In other words, in a given case the meningitis may not be so generalized as the severe symptoms seem to indicate, and, in consequence, a prompt operation may relieve the patient. In any event, we are developing the subject in the right direction, and, while diversity of opinion exists as to the curability of certain forms of this disease, the conviction is unanimous that otitic suppurative meningitis can be cured only by the institution of immediate operative intervention. Briefly, then, otitic meningitis is strictly a surgical disease, just as suppurative peritonitis has long since been so recognized; and, in consequence of the growing demand for this interpretation, the profession will, sooner or later, be brought to a realization of this fact.

In the treatment of otitic meningitis, then, two objects are paramount: the first, the complete removal of

*Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

1. Heine: Operations on the Ear, 1908.

the primary source of infection; and the second, the complete evacuation of the intradural exudate. From the fact that the usual route of infection is through the labyrinth and internal auditory meatus, our efforts obviously must be directed toward the establishment of drainage in all cases of this nature. When prompt surgical measures are adopted many patients with "meningitis serosa," even though diffuse, will recover, but from the fact that death is caused from paralysis of the respiratory center, due to pressure, an early operation is imperative. Drainage, once established, must be maintained by the adoption of every means to this end at our command, and, even then, little hope can at present be entertained for the recovery of a patient with diffuse suppurative meningitis, when the symptoms are mainly toxic.

Whenever we have confined pus or other inflammatory exudate our first object in the line of treatment is its immediate evacuation by the establishment of efficient drainage. In otitic basal meningitis this is best accomplished by either the translabyrinthine operation, in which a coincident vestibulotomy is an essential part, or by the postlabyrinthine operation, and, in certain selected cases, it may be necessary to perform both of these operations. On this subject West and Scott² remark:

It is yet too early to speak with certainty on the prospect which this operation (translabyrinthine) holds out of saving the less virulent cases of meningitis. We can say only that we have, by its use, combined with lumbar drainage, succeeded where previous experience with cases of similar type led us to expect a fatal result, and that we regard it as a method of great promise. It has two obvious advantages over postlabyrinthine drainage, namely, that the route of infection is strictly followed and that the internal meatus affords a natural drainage-tube, which is infallibly rightly placed, and leads directly to the part of the subarachnoid space which it is desired to reach. In addition there is the great gain that the primary source of meningeal infection is removed.

In localized meningitis, complicating acute aural disease, we must first perform the simple mastoid operation, taking care to remove every trace of necrotic bone, while the radical operation is necessary in cases resulting from a chronic purulent otorrhea. Great care must be taken not to disturb the barrier hastily established by Nature to inhibit further ingress or dissemination of infectious micro-organisms, and yet every vestige of bone must be removed down to the area of adhesion between the dura and bone, but not beyond these limitations.

In a former communication on this subject I pointed out the importance of always carefully opening the external labyrinthine wall for a fistulous opening, as an essential part of the mastoid operation. In severe meningitis, of whatever type, this opening must be enlarged and the semicircular canal, vestibule and cochlea opened to provide efficient drainage from the labyrinth.

Meningitis occurring by way of the labyrinthine route is always secondary to a necrotic disease of the middle ear and accessory cavities. The mode of infection, therefore, is usually through the fenestra rotunda, the fenestra ovalis, the promontory, or the horizontal semicircular canals. This invasion may also occur by way of the aqueductus vestibuli, the aqueductus cochlea, or the posterior or superior canal.

In all cases of diffuse otitic meningitis, serous or septic, the radical mastoid operation should be performed immediately. This will frequently expose the

focus of bacterial invasion, manifested by eroded bone or exposed dura, through which a free incision should be made to provide for evacuation of the intradural exudate. Although a diffuse suppurative meningitis will most likely prove fatal, our only hope of relief lies in the prompt adoption of the surgical measures above enumerated, and, in addition thereto, drainage of the lateral ventricle. The form of septic meningitis which is most likely to recover is that caused by the staphylococcus.

Infections of the meninges with the *Micrococcus pneumoniae*, in my judgment, are always fatal, and especially is this true when such infections complicate a pneumococcic otitis media, which is much more prevalent than the literature of the subject would seem to indicate. Indeed, my experience in the past few years has forced me to the conclusion that a pneumococcal aural infection is not only one of the most destructive in its ravages on the soft and osseous structures, but probably more prone to the development of secondary otitic meningitis than any other form of germ infection. In fact, the ear is so often involved during a pneumococcic, as well as a typhoid infection, and the complications incident thereto so frequently occur, that the profession should always be mindful of their intimate association. This seems especially true when we are reminded of the large number of such aural complications that are never suspected until a suddenly discharging ear reveals to the attending physician a condition replete with danger.

Then again, the ultimate recognition of these complications very frequently clears up a doubtful diagnosis in a given case, and in another forcibly demonstrates that, after all, the patient was not suffering from a so-called relapse. This pointedly illustrates the importance of a bacterial invasion of the organ of hearing in its relation to many general diseases, either as a complication or as the chief underlying, unrecognized, etiologic factor.

As in other forms of illness, we must use every means at our command to establish a precise diagnosis, not only as to the presence of meningitis, but, if possible, the exact form and extent of this disease, as successful intervention can only be accomplished by the adoption of prompt surgical interference. Our treatment and prognosis, therefore, will be governed entirely by our ability to establish a prompt diagnosis. Lumbar puncture is probably our best means of accomplishing this end, which also has the advantage of exerting a favorable influence on the cerebrospinal pressure, as in the presence of acute serous exudates this procedure (repeated if necessary) is of distinct therapeutic value.

Normal cerebrospinal fluid is absolutely clear and entirely free from all foreign matter. If, therefore, we are in doubt as to the necessity for operative interference, and lumbar puncture reveals a cloudy fluid containing cellular elements and fibrin, we are assured, in the first place, of the presence of a meningeal inflammatory exudate, and, in the second place, of a very doubtful prognosis in the absence of prompt surgical intervention.

Serous meningitis need not necessarily be caused by the various forms of bacteria, as demonstrated by lumbar puncture; or, when present, these may be very few in number, or their virulence greatly reduced, and the case may not, therefore, call for operative interference.

If the symptoms of intracranial pressure are grave a decompression operation should be performed over the

2. West and Scott: The Operations of Aural Surgery, P. Blakiston's Son & Co., Philadelphia, 1909.

cerebellar or temporal regions, following which it may be necessary to incise the dura. In addition to this, drainage of the lateral ventricle should be resorted to. This latter procedure is often used only as a last resort, but it would probably be of greater service if used at the onset of pressure symptoms that cannot be relieved by lumbar puncture.

THE OPERATIVE TREATMENT OF OTITIC MENINGITIS *

HOLGER MYGIND, M.D.
COPENHAGEN, DENMARK

. My topic is the operative treatment of otitic meningitis. By meningitis I mean here diffuse purulent leptomeningitis, that is, an acute inflammation of the soft membranes of the brain which has produced a cerebrospinal fluid varying from being slightly turbid to mere pus, and containing an excess of polynuclear cells. The so-called serous meningitis and the different forms of local meningitis are, therefore, excluded in this paper.

The operative treatment of otitic meningitis, in contradistinction to operations for other otitic intracranial complications, has made its way very slowly. It was, as you know, initiated about eleven years ago by Macewen of Glasgow, who, in his excellent work on pyogenic diseases of the brain and the spinal cord, published a report of two cases of otitic meningitis in which operation was successfully performed. I do not think, however, that these were genuine cases of diffuse purulent meningitis. Since then, several surgeons have tried surgical interference in otitic meningitis, and a small number of successful cases have been reported. But even now, one of the leading otologists in Germany, Herman Schwartze of Halle, still abstains from operation in cases of otitic meningitis, as can be seen from the last report from his clinic published a few months ago.

There are, I think, several reasons for the fact that this operation makes its way so slowly. First, surgeons often get these cases under treatment when the meningitis is far advanced and the whole state of the patient is such that one involuntarily thinks of Dante's words, "Leave hope behind, all ye who enter here." Second, I think that other surgeons may, like me, have operated on a number of consecutive cases of even short duration without being able to avert a fatal issue. I myself operated on my first ten patients without success. After such an experience, it is very natural for a surgeon to abandon the operation, especially as the operative treatment of other otitic intracranial complications has yielded such unexpectedly good results.

Third—and this is perhaps the principal cause—aural surgeons, even with an extensive practice, do not see many cases of otitic meningitis. For example, an experienced aural surgeon, Dr. Dench, who read a most interesting paper on the operative treatment of otitic meningitis at the International Medical Congress last year, up to that time operated on only eleven cases of otitic diffuse purulent meningitis. In my department of the large municipal hospital of Copenhagen, a city of over one-half million of inhabitants, an average of only seven patients suffering from otitic meningitis are admitted in the course of a year,

although a considerable number of real or supposed cases of otitic intracranial complications are sent to the hospital, which is open to every one, rich and poor.

The material on which this paper is based is, therefore, small, for, during the last four and one-half years during which I have operated for otitic meningitis, only thirty-three cases of this disease have come under my observation. In twenty-six of these operation was performed. I have operated on several patients who I believed, at the time of operation, had otitic meningitis, but in whom the post-mortem revealed tuberculous meningitis or edema of the meninges. I believe, however, that my material on this topic is the largest of which a report has as yet been published.

Before entering on the principles and the description of the operation of otitic meningitis I would strongly urge the importance of performing, if possible, before operation two forms of examination, lumbar puncture and examination of the acoustic and static functions of the labyrinth. Both forms of examination are not only valuable for the diagnosis, the prognosis and the etiology, but also for the treatment of this disease.

It is well known that the diagnosis of otitic meningitis is extremely difficult in many cases, and if it were not for lumbar puncture many more diagnostic failures would be made than at present. Like most other diagnostic methods, it is not infallible, but the exceptions are very rare. Its principal drawback is that cerebrospinal fluid is not always evacuated, or is united with blood, which renders the examination worthless. I have made use of lumbar puncture over 200 times and consider it, if all proper septic precautions are taken, a safe procedure; only once or twice was it followed by unpleasant consequences in the form of pains in the back and in the legs, which pains, however, were only of short duration. The more I use the lumbar puncture the more I rely on it as a diagnostic method.

My experience in the use of lumbar puncture shows that in all cases of otitic meningitis the cerebrospinal fluid is turbid twenty-four to thirty-six hours after the onset of the meningitis, but rarely earlier than twenty-four hours after the onset; it contains cells of which the majority are polynuclear. Bacteria are generally present; when they are absent the prognosis is favorable. The more turbid the fluid the worse the prognosis. On the other hand, the clearing of the fluid during treatment is a sure sign of the retrogression of the meningitis, and in several of my cases it showed itself before the brain symptoms began to clear up.

I often perform a lumbar puncture without any general anesthetic, but in cases in which I am convinced that the patient has intracranial disease I often postpone this procedure until the patient is under the anesthetic for the operation. If the microscopic appearance of the fluid leaves any doubt a microscopic examination is performed by an assistant during the first stage of the operation.

I have tried repeated lumbar punctures in a few cases, as a therapeutic agent in otitic meningitis, but have not observed any beneficial result.

The examination of the acoustic and static function of the labyrinth is also valuable, both in diagnosis and in deciding on the nature of the operation to be performed. Total deafness and the absence of nystagmus when the diseased ear is syringed with cold water, after Barany's method, point strongly to meningitis in doubtful cases, and demand the opening of the labyrinth during the operation.

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

I shall now proceed to the question whether or not operation shall be performed in all cases of otitic meningitis. My answer must be that only in a few exceptional cases, namely, those in the advanced stages of the disease, should I feel justified in advising against operation. And even then, in children and young persons suffering from otitic meningitis, a comatose state may be the result of an abscess in the brain rather than of the meningitis it has caused, for brain abscess is by no means a rare cause of meningitis, and its symptoms are often entirely concealed by the symptoms of the meningitis. Furthermore, in my experience, in fatal cases the patient seldom grows worse immediately after the operation; more frequently the brain symptoms become less pronounced, but in most cases the state remains unchanged. Thus nothing is lost by operation and the patient is given a chance of recovery.

Operation for otitic meningitis ought to be performed without loss of time. Each hour that passes before operation may be fatal. My impression is, that in a certain number of cases of meningitis, the inflammation of the membranes of the brain does not set in, as in the majority of the cases, with a sudden explosion like that of a gunpowder barrel into which a spark has fallen, but resembles rather a smoldering fire, spreading for a short time to all sides and bursting at last into an all-destroying conflagration. In such cases, if the primary disease is eliminated early, the fire dies out for want of fuel.

The elimination of the primary focus in the ear is beyond doubt the salient point in the surgical treatment of otitic meningitis, and this should be done as thoroughly as possible. This involves the opening of the labyrinth in all cases in which either the functional examination before the operation shows that it is destroyed or the examination during the operation shows that it is diseased, the most frequent sign being the existence of a labyrinth fistula. In order to get the external wall of the labyrinth well exposed for inspection it is necessary to perform a radical operation also in cases of acute osteitis of the mastoid process. It is, besides, easier to perform craniotomy over the tympanic cavity after radical operation.

After having performed a radical operation and eliminated all diseased tissue in the temporal bone, where there generally is an acute osteitis even in chronic cases, the disease being very seldom limited to the antrum mastoideum alone, there is another frequent inflammatory focus to be looked for carefully, namely, thrombosis of the sigmoid sinus. My experience proves that it is a frequent complication of middle-ear disease in these cases, the sinus being found diseased in eight out of my thirty-three cases. I think that, in a certain number of cases, it is probably the medium through which the inflammation spreads to the membranes of the brain. The presence of this intracranial complication does not, according to my experience, make this prognosis more grave. On the other hand, I believe that there are also cases in which the inflammation from the middle ear spreads explosively to all sides, reaching simultaneously the membranes of the brain and also, sometimes, the brain itself, where it forms an abscess or an acute encephalitis.

In all cases of otitic meningitis, therefore, I expose to view the whole perpendicular part of the sigmoid sinus and examine it for the possible existence of a thrombosis. It is, however, by no means an easy matter to diagnose the existence of a thrombus by ocular examination or by palpation of the sinus. Neither does the history of a

case often give any hint of the presence of thrombophlebitis. For these reasons I generally make a puncture of the sinus with a Pravaz syringe. If this reveals fluid blood in two different places a little apart from each other it is highly probable that there is no thrombus present. If the syringe remains empty or if pus is extracted I do not open the sinus and expose the lateral wall during this stage of the operation, but I wait to do it at the end of the operation, when craniotomy is performed, in order to avoid infection of the soft membranes of the brain from the diseased sinus, in case it should be found necessary to open the subdural space. In these cases, as a rule, I do not ligate the jugular vein, partly because I have not faith enough in the beneficial effect of this operation in the majority of cases of thrombophlebitis and partly because I fear that ligation of the internal jugular veins produces an unfavorable circulation in the diseased brains. Furthermore, the ligation prolongs the narcosis, which is often very long, especially if the labyrinth is opened.

I now perform craniotomy by enlarging upward the bony cavity produced by the radical operation, using as much as possible a strong cutting forceps and making an opening extending $2\frac{1}{2}$ inches horizontally and about $1\frac{1}{2}$ inches vertically. The opening should be so situated as to expose freely for examination the following parts of the dura: first, the part corresponding to the mastoid antrum; second, that part corresponding to the attic, for the inflammation of the soft membrane of the brain occasionally starts here as a local pachymeningitis; and, third, the part of the dura which covers the posterior surface of the petrous bone, for there are found now and then small, deep-seated epidural abscesses which otherwise are easily overlooked. When looking for this form of abscess the free exposure of the sigmoid sinus, performed in the former state of the operation, is of great assistance, as the inner edge of the perpendicular section of the sinus represents a line beyond which one must not go.

The question now arises, should the subdural cavity be opened in all cases of otitic meningitis? I must at once declare that I am not able to give a decided opinion on this point at the present state of our knowledge of the subject. I think it is still a matter *subjudice*. That it should be done in a certain class of cases is beyond all doubt. These cases are the following: (1) when a fistula is found in the dura, for then there is sure to be either a pure subdural abscess or a subdural abscess complicated with a superficial abscess of the brain (what Macewen calls an ulceration of the brain); (2) when there are signs of gangrene of the dura, which shows itself by a part of the cranial surface of the dura being discolored, soft and uneven on the surface, and in which case it is highly probable that there is a suppurative pachymeningitis interna with or without superficial abscess of the brain; (3) when the subjective or objective symptoms point toward the existence of a brain abscess; this must be suspected especially when brain symptoms have existed previously to the development of meningitis, when there is slow cerebation and when there are local symptoms. It is, however, an established fact that meningitis may be accompanied by local symptoms without an abscess of the brain being present.

When the dura presents a normal appearance or is covered with superficially healthy granulations or other products of a pachymeningitis externa which do not point toward the existence of a deeper lesion of the membrane (for instance, fibrous filaments), the question

whether an incision of the dura should be made or not is, in my opinion, very difficult to decide. The incision of the dura has, of course, its great advantages and I myself have performed it in most of my cases, but experience has shown me that it also has serious drawbacks. The advantage which at once presents itself as important is the possibility which the opening of the subdural cavity gives for this drainage and the subarachnoidal spaces, and many surgeons attach much importance to this procedure, believing it to be a most important factor in the treatment of otitic meningitis. My personal experience does not, I must confess, corroborate this view. I have in several cases drained the subdural cavity by means of iodoform gauze and found that the drainage was often imperfect, presumably because the hyperemia of the brain or the superficial encephalitis,¹ so often present in meningitis, makes the brain swell so much that it is pressed hard against the inner surface of the skull round the craniotomy opening, a phenomenon one often can observe directly after craniotomy is performed. In other cases the secretion is enormous and can be tolerated by the patient only if he is able to assimilate a corresponding quantity of fluid through his intestinal tract. Besides, while in some patients the substance of the brain is very tolerant of meningitis, in others the slightest touch produces bleeding and contusion. I am, therefore, not convinced of the advantage of draining the subdural cavity in ordinary cases of otitic meningitis.

But the incision of the dura as a routine treatment has one great advantage: it insures the operator against overlooking a subdural or a cerebral abscess, which complications now and then do occur in cases of otitic meningitis. For instance, among my operations, which number twenty-six, two were in cases of subdural and three were in cases of cerebral abscess; and in two of these the dura showed no sign of disease on its cranial side, nor did the patient in these cases exhibit any symptoms of these complications. Therefore, when the dura has not been opened the surgeon remains in uncertainty as to the existence or non-existence of a subdural and a cerebral abscess in cases in which the brain symptoms do not decrease after operation, and he must now and then be obliged, as I once have been, to open the subdural space a day or two later. This operation is, of course, very easy and of short duration where craniotomy once has been performed, but it may be performed too late to check the development of the meningitis.

It will be seen that several circumstances speak greatly in favor of the opening of the subdural cavity in all cases of otitic meningitis. But it has two serious drawbacks should no subdural or cerebral abscess be found, namely, the risk of infecting a healthy brain and of producing a prolapse of the brain. Prolapse of the brain is in aural cases, according to my experience, often a very difficult complication to deal with during the after-treatment. It easily obstructs the cavity produced by the operation, making the dressing of it difficult, and the brain substance in some cases becomes infected from the suppurating cavity of the temporal bone.

Having given my opinion on the principles of the operative treatment of otitic meningitis, I shall conclude by stating the results I have obtained.

Of the thirty-three patients with otitic meningitis who form the basis of this paper, exact diagnosis in all cases being insured either by lumbar puncture or by post-

mortem examination or by the fatal termination of the disease, seven were not operated on, most of them because the patient or their relatives refused operation. They all died. Of the remaining twenty-six, the operation performed was without any result whatever in seventeen cases. In one case, that of a girl aged 7, the patient woke up at once from a comatose state and seemed on the way to perfect recovery, when suddenly, nine days after operation, cerebral hemorrhage occurred and the patient died. In two cases all signs of the meningitis disappeared entirely, but an abscess of the brain developed later and the patients died, respectively, one month and about one-half year after the operation. In the remaining six cases there was complete recovery, one patient, however, having still a prolapse of the brain covered with epidermis one year after operation. To illustrate the benefits of the operation I will give a short history of one of these cases.

A woman, aged 28, was sent to my department last year after having suffered for a few days from headache and drowsiness, accompanied by fever. She lay in a deep sleep, from which she could be roused only with difficulty, showing signs of slow cerebation, with a pulse of 50. There was complete paralysis of the right oculomotorius and a slight central paresis of the left facial nerve. There was a chronic suppuration of the right middle ear with no mastoid infiltration or tenderness. Neither rigidity of the neck nor the sign of Kernig was found on admission, but both appeared two days later. The lumbar puncture yielded a very turbid cerebrospinal fluid, which contained numerous polynuclear cells, but no bacteria. Radical operation of the middle ear was performed at once with craniotomy incision of the dura and incisions of the brain in different directions, an abscess being suspected, but not found. The next day this markedly slow cerebation changed to excitation, which lasted for some time. Four days later the cerebrospinal fluid was almost clear and the patient was ultimately perfectly cured, a cerebral prolapse which developed after the operation disappearing again entirely.

Such a case is a good illustration of the beneficial effect of the operative treatment of otitic meningitis in some cases. This young woman was the eldest of my patients who recovered, the others being mostly young persons about the age of puberty. In several cases the symptoms indicated a very serious disease of the brain and the turbidity of the cerebrospinal fluid was in most cases very pronounced, but in all the cases the meningitis had been of only a few days' duration.

I must finish this paper, which I have endeavored to make as short as possible, by urgently recommending that you never consider a case of otitic meningitis as a *noli me tangere*, but that you operate without loss of one of those precious moments on which may hang the life of a human being.

ABSTRACT OF DISCUSSION

ON PAPERS OF DES. DENCH, SMITH AND MYGIND

DR. NORVAL H. PIERCE, Chicago: Our distinguished guest has handled the subject much more simply than we in America are accustomed to regard it. I listened attentively and endeavored to understand on just what symptoms he bases the diagnosis of a general purulent meningitis. I believe it is very important to maintain a difference in our minds between serous meningitis and purulent meningitis. On this point depends what Professor Mygind said regarding the incision of the dura. My opinion is, or rather I accept the opinion, that a serous meningitis is nothing more nor less than a collateral edema due to the action of toxins on the fluid and tissues constituting the sub-dural space, resulting in an increase of the cerebrospinal fluid. A purulent meningitis, on the other hand, is an entirely different thing; a

1. In some cases I excised a piece of the brain and had it microscopically examined, with the result that there was found no evidence of encephalitis.

purulent meningitis has to do with the action of living micro-organisms on the blood vessels and the perilymphatic spaces accompanying these vessels of the meninges—especially of the pia, which provides vessels and perivascular lymph spaces which penetrate the brain substance—so that in all cases of purulent leptomeningitis we have an encephalitis as well. It is impossible to differentiate clinically between certain forms of serous meningitis and purulent meningitis. Fever, pulse, stiff neck, general condition, slow cerebration, delirium; are to be found in both classes; nor can we place absolute dependence for our differentiation on lumbar puncture. You may get a cloudy fluid very rich in leukocytes on lumbar puncture and yet have a serous meningitis that is due to a localized purulent focus within the epidural space which has been walled off. The corpuscular elements sink to the bottom of the cerebrospinal sac as they would in a test tube. That we may have a cloudy fluid on lumbar puncture in cases of serous meningitis is abundantly proved by the observations of Koerner, Alexander, Voss and others.

Our visitor has said that he is careful to examine the static functions in order to ascertain whether the labyrinth is involved in the purulent process. Undoubtedly this is very important, but we must also remember that if he uses this in support of his position that he has to deal with a general purulent meningitis, his deductions may be erroneous. The cases in which the meninges are invaded by way of the labyrinth have no tendency *per se* to become diffuse purulent meningitis; their tendency rather is to become localized and encapsulated.

Now regarding treatment, a serous meningitis may be due to suppuration outside the cranial cavity, as in acute otitis media in children; it may be due to a localized purulent focus inside the cranial cavity but outside the dura, as in extradural abscess; or, it may be due to a purulent focus inside the dura which has become walled off. When we can remove the irritative focus we cure the collateral edema. Now, are we not in great danger in such cases following immediately the operation on the mastoid of incising these dura, in an area that is already highly septic (because most operators recommend puncture of the dural sac from the mastoid wound), of changing a simple serous meningitis into a diffuse purulent meningitis by introducing micro-organisms within the subdural space? At least this is one of the dangers of which we must beware.

Dr. J. A. STUCKY, Lexington, Ky.: Notwithstanding the eminence of the essayists and their great experience, their care and judgment and scientific ability, the subject under consideration still remains one of the unsolved problems, but undoubtedly we are progressing, and are saving more meningitis patients to-day than we did five or ten years ago. I see a great many cases of meningeal irritation of otitic origin, the result of long neglected ear troubles. A few years ago I spent some time with Ballance at London and came home enthusiastic for his teaching; out of 17 carefully observed and recorded cases I have seen 3 or 4 recoveries. As Dr. Pierce has said, in the question of diagnosis of cerebral edema (and I may say that I believe in a serous meningitis; that the serous form is simply a prepurulent stage), we may have more than one cause of infection. No one has mentioned the danger of confusing what our presiding officer called a meningismus with a meningitis. We may have a toxemia that produces all the symptoms of the serous form, or a diffuse meningeal irritation, or a meningitis; I have seen that from intestinal toxemia. We know that there is no disease that locks up the secretory and excretory functions of the body like a disease of the ear, and in our efforts to diagnose these cases by exclusion we must not forget the possibility of intestinal toxemia producing a meningeal irritation. Neither of the essayists, nor Dr. Pierce, has mentioned the possible good results that may come from the administration of large doses of hexamethylenamin in these cases of suspected meningeal irritation. I think it is well to consider that in the treatment. I endorse with emphasis what our distinguished guest has said—give your patient a chance—no case is hopeless—operate early and give drainage.

Dr. C. M. BROWN, Buffalo: It seems to me that Dr. Dench struck the keynote when he said that the important thing was early diagnosis. I would call attention to one symptom that has not been referred to, that is restlessness or twitching of the muscles of the face. Alexander claims that this is more important than stiffness of the neck. I would like to ask Dr. Dench if he has observed this?

Dr. R. P. SCHOLZ, St. Louis: I believe that all authorities agree that in cases of suppurative meningitis of otitic origin, operation is indicated, and that patients with serous meningitis, or as one of the speakers has called it, collateral edema, may recover without surgical interference. In rare cases Nature often brings about restitution where there has been suppuration of the labyrinth with more or less meningeal involvement. I believe the post-mortem room furnishes the best opportunity for study of this class of cases, for here we see not only the cases resulting in death from meningitis, but occasionally find a case in which there is evidence of an old healed meningitis. I have observed that in cases of meningitis, exudate is frequently found about the lamina tectoria cerebella and believe that this and congestion occludes the foramen of Magendie, thus giving rise to increased ventricular pressure. I would like to ask Prof. Mygind if he too believes that all such cases in which there are inflammatory changes (exudate, etc.) about the foramen of Magendie, are not necessarily fatal.

Dr. OTTO GLOGAU, New York: A patient came into the office with the statement that he had been in a hospital, had had a mastoid operation, had been neglected and there was development of granulation tissue about the wound. I called in consultation another otologist, who decided that it was exuberant granulations, while I had suspicion of a malign growth and removed a piece for microscopic examination. Dr. Neuman of Vienna saw the case, and without looking at the mastoid wound decided that an operation should be done, the patient having all the symptoms of otitic meningitis; but the next day when I took off the dressing he decided that it was an inoperable sarcoma of the mastoid and it turned out to be a spindle-celled one. I asked Dr. Coley for some fluid and learned that he had seen the case before, a fact which the patient had not told us. The patient had, a few months before, a slightly swollen gland underneath the mastoid, attended with pain, which was mistaken for mastoiditis and operated on. He developed a sarcoma which had encroached on the dura and from this growth was produced an attack of otitic meningitis.

Dr. CULLEN F. WELTY, San Francisco: It has been demonstrated that in 65 or 75 per cent. of all cases of meningitis infection comes by way of the labyrinth. This is really startling; but there are tests which, if made in detail, will tell the exact condition of the individual labyrinth. Should this examination be put off the patient may be so ill that a satisfactory examination cannot be made later.

The examination chart of the Vienna school of otology is as follows:

A.	B.	R.		L.	A.	B.

If from examination a latent labyrinthitis is diagnosed and a meningitis develops, it is clear that the complete destruction of the internal ear is essential; in other words, the Neumann operation. However, if a meningitis develops and the labyrinth is intact, one knows that a different operation should be done. The possibilities in such cases are much lessened—one has much more definite information and can proceed accordingly.

The Vienna school of otology has certainly reduced the mortality of meningitis in this very way. They further teach and show conclusively that one is not qualified to do the radical ear operation unless he is prepared to do the complete exenteration of the labyrinth, and that a patient with a labyrinth suppuration should not be operated on at all unless the labyrinth is destroyed at the time the mastoid operation is done.

A few of these points are very well illustrated in a recent case to which I was called in consultation. The patient had a marked nystagmus to the opposite side; Weber to the good ear, and as I supposed, some hearing. Fistula test was negative. By the syringing with cold water, I concluded that the nystagmus was increased; this, however, was questionable; at all events my confrères agreed that such was the case. A diagnosis of circumscribed labyrinthitis was made and the radical operation done; at operation a fistula of the horizontal canal was found, the facial uncovered by caries, all of which was in perfect accord with the diagnosis. Three days later the patient was comatose, with stiff neck and painful spine. The labyrinth examination was made again and more accurately. There was no hearing and no increase of nystagmus from cold water, Weber to good ear. At this time the family would not allow further operative procedure. The patient recovered, she had a serous meningitis and it was induced by the operative procedure. The labyrinth should have been removed at the time of the first operation. So it is plain how important an accurate examination would have been in this particular case.

DR. E. B. DENCH, New York: With reference to Dr. Brown's question, I have not observed the restlessness and twitching of the facial muscles spoken of. I have seen beneficial effects follow repeated lumbar puncture. In reference to the exenteration of labyrinth in case of fistula, I presume Dr. Mygind means only where there are meningeal symptoms.

Puncture of the lateral sinus as a diagnostic measure has not proved satisfactory in my experience; one may go through a parietal clot and get fluid; I would rather open it than make a puncture in it. I agree with him as to the danger of ligating the internal jugular vein. In one case I think I got a death in this way.

Whether or not the dura shall be incised depends on the severity of the symptoms; if mild let the dura alone, but if severe, with high temperature, and pressure symptoms, you must incise the dura and pack it off.

In reference to Dr. Pierce's remarks as to the danger of the decompression operation on account of infecting previously healthy brain tissue, it seems to me that if it is done far forward, through the thinnest part of the squama, you can keep well away from the infected area and I do not think there is very much danger if you are careful to keep the wound in the mastoid thoroughly packed.

DR. S. MACCUEX SMITH, Philadelphia: I shall occupy only a few minutes to somewhat justify my digression from the subject of this symposium to state that I feel it is of the greatest importance for the general physician to keep the following cases in mind.

About three weeks ago, within a period of thirty-six hours, I was called to see three cases of otitic meningitis in adults, all of which proved fatal. One of these patients died before my arrival; two died within half an hour of my seeing them. In none of the cases was the ear recognized as the underlying etiologic factor sufficiently early to warrant operative intervention.

In one case I freely incised the membrana tympani and evacuated a quantity of pus which escaped under considerable pressure. This I did with a view of clearing up the diagnosis, about which there was still much difference of opinion. None

of these cases complained directly of pain in the ear, but they did complain of considerable head pain on the corresponding side, mostly over the temporal region, which was looked on as neuralgia. In only one of the cases did a discharge appear from the ear before death, through a spontaneous rupture of the membrana tympani.

DR. HILGER MYGIND, Copenhagen, Denmark: There is not a single symptom, subjective or objective, which is pathognomonic of meningitis. I have seen fatal cases where, until death, there was no rigidity of the neck and no Kernig sign, although the sign of Kernig is almost the most certain that we have, but I have seen two cases in which the sign was absent until death, and on the other hand I have seen cases of hyperemia of the brain in which it was present, though only very slightly. So, I think there is not a single certain subjective or objective sign. There is only one certain method of diagnosis, and that is by means of lumbar puncture.

Another question is, What is serous meningitis and what is purulent meningitis? Well, I think we shall not waste much time discussing that, because it is merely a matter of words. Let us first agree on what is a serous meningitis. If you go to three different competent men you will hear three different opinions as to what serous meningitis is. If you want my opinion I will say this: It is an acute disease of the brain with symptoms, subjective and objective, of meningitis, where the spinal fluid is clear but containing polynuclear cells when examined under the microscope. That is my definition. To call a case serous meningitis when there is no serous appearance of the fluid is confusing; so I think this definition I have given may help. I will not say it is the right one, because I might come to the next meeting with a different opinion; it is *sub judice*. We are in the first stage of our knowledge and are experimenting. If the fluid is turbid and contains an excess of polynuclear cells we have evidence of an inflammation of the meninges. Dr. Pierce may say that it is localized. Well, I have seen several cases of localized meningitis and in not a single one was there any alteration of the cerebrospinal fluid. I will not say that such cases do not occur. As I said in my paper, the puncture is not invariable, but the exceptions are rare. So I think we are justified in calling such cases as I speak of serous meningitis. This is a matter of opinion, which is, of course, not of so much practical importance, but the question of how to treat the case is of great importance.

I have been much interested in hearing the experience of Dr. Dench and the other gentlemen on this matter, and I am prepared to alter my opinion. If Dr. Dench can show me a proceeding by which I can prevent the production of a prolapse, then I shall not be so afraid of opening the subdural space as I have been lately. But, as I told you, I operated in nearly all my cases in that way in the beginning, though my experience has told me that the proceeding is not without danger.

A POSSIBLE DIFFERENTIAL SIGN BETWEEN CARDIAC DILATATION AND PERICAR- DITIS WITH EFFUSION*

W. J. CALVERT, M.D.

Professor of Medicine, Baylor University School of Medicine
DALLAS, TEXAS

In attempting to develop a differential sign I wish to acknowledge the dangers of generalizing from my limited material and of interpreting post-mortem findings as clinical signs.

While studying the details of the mechanics of the support of the normal and pathologic heart, some relations between the heart, right lung and liver turned my attention to the changes in the position of the liver due to dilatation of the right heart and to pericarditis with

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

effusion. On analysis these changes seemed to be due to certain physical forces producing strains on given anatomic structures. As the nature and direction of these stresses are constant, varying only in degree, their effect should also be constant, varying only in degree. In the two lesions the physical forces present differ in that the support rendered the liver by the inferior cava through its connection with the heart and the connective tissue structures extending from the heart to the neck, is applied farther to the right in dilatation than in pericarditis. This difference in support of the liver may, when pressure is applied from above, cause a displacement of the liver to a degree possibly sufficient for a differential sign. The differential sign in cardiac dilatation is a high liver with a narrowed area of lung-liver relative dulness, and in pericardial effusion, a low liver

and side view. In this way the position of each organ and its relation to neighboring organs can be quite accurately studied. The strain on certain parts of organs can also be determined by considering the direction of parts in the light of the forces at work.

Examples of extreme development of given conditions often call attention to principles which might otherwise be overlooked. Consequently two cases will be described: first, a case of extreme dilatation of the right heart due to mitral stenosis; second, a case of extreme collapse of the heart due to pericarditis with effusion.

DESCRIPTION OF CASES

Points of Interest in Case 1

Sternum and ribs markedly depressed.

Heart as a whole displaced slightly into left thorax.

Fig. 1.—Mitral stenosis (Case 1) dilatation of left auricle, right ventricle, and auricle; position of heart (H) above reaching first rib, below, tip of ensiform cartilage, to left 9.5 cm., to right 8 cm.; right lung (L) 6.5 cm. to right of midsternal line, lower border in front in fourth interspace; liver (Li) enlarged, right lobe high, at fourth rib, hepatic veins open into right auricle at highest portion of right lobe, left lobe depressed; inferior cava, (IC) displaced to right with convexity to right.

with a narrowed area of lung-liver relative dulness. This possible differential sign pertains only to large cardiac dilatation involving the right heart, from which a differential diagnosis of pericarditis with effusion is often most uncertain.

Full details leading to the essential physical and anatomic reasons for this difference in the position of the liver are too numerous to be given in a paper of this nature. Consequently the main facts will be stated, leaving details for future publications.

The material was fixed in formaldehyd solution, sectioned, measured, and each organ projected in a front

Fig. 2.—Pericarditis with effusion (Case 2); pericardial sac, P (dilatation not shown); heart, H (collapse cannot be shown); right lung (L) slightly displaced to right; pleural adhesions which have been pulled downward by pericardial pressure; liver (Li) displaced downward, upper surface of right and left lobes in almost same plane; inferior cava, (IC) not shown, but runs in almost a straight line.

Valvular openings actually lower than normal but when located in terms of ribs they are only slightly displaced, especially when the size of the heart is considered.

Left ventricle about normal size.

Left auricle greatly dilated. Greater portion of right wall in front of the root of right lung.

Right ventricle greatly dilated. Has pushed left lobe of liver downward.

Right auricle greatly dilated.

That portion of inferior cava above diaphragm dilated to form part of the right auricle.

Auriculoventricular wall runs in almost a straight line from diaphragm to root of left lung; this includes a portion of the wall of the left auricle.

Hepatic veins run in almost a perpendicular direction and open at the highest portion of the cupola of the right diaphragm into the right auricle.

Inferior cava dilated, displaced to right with convexity to right.

Liver (enlarged) has been pushed to right by the dilating right auricle and inferior cava. The right lobe has been held by the walls of the right auricle and inferior cava. This is shown by direction of walls and the course of the hepatic veins. Right lobe much higher than left—cupolated effect. Right lung pushed by left and right auricle upward, outward and backward.

Points of Interest in Case 2

Sternum and ribs only slightly depressed.

Heart swings near median line.

Valvular openings only slightly displaced.

All heart chambers collapsed.

Inferior cava above diaphragm stretched and that portion within the pericardium collapsed; near median line; congested but not greatly dilated.

Fig. 3.—Pericarditis with effusion and dilatation of right heart (H); outline of pericardium (P) shown; liver (Li) at fifth rib, right lobe slightly higher than left; D, diaphragm; L, lung.

Auriculoventricular wall almost a straight line.

Liver displaced downward; right lobe not held up as in Case 1; right and left lobe in almost the same plane.

Right lung pushed outward and backward by the pericardial sac; pleural adhesions prevent easy displacement of lung; these adhesions show signs of downward drag.

COMMENT

These findings lead one to believe that the attachment of the pulmonary veins to the connective tissues and other structures about the root of the lungs and the auriculoventricular wall attached to the large vessels and through the left auricle to the root of the lungs play an important rôle in the support of the heart. When the right heart is markedly dilated the auriculoventricular wall runs in almost a straight line from the dia-

phragm to the root of the left lung, thus indicating the support of hydraulic pressure and stress transmitted from diaphragm to the root of the left lung. The right wall of the right auricle and to some extent the right wall of the pericardium transmit to the root of the right lung a portion of the stress from the diaphragm. Fibrosis incidental to cardiac lesions increases the strength of the auriculoventricular wall.

As the heart dilates the central tendon of the diaphragm is lowered; the weight of the liver and the resistance offered the dilating heart are referred to the walls of the right auricle and the auriculoventricular wall, thence to the root of the lungs and to the neck. Doubtless the column of blood materially supports the vascular and cardiac walls. The support thus rendered the liver is applied in Case 1 at the openings of the hepatic veins in the inferior cava. The support thus given the liver prevents the actual depression of the

Fig. 4.—Aortic stenosis; right heart slightly dilated; liver very large and high.

right lobe to the same degree as that of the left. Consequently the right lobe is pulled up, producing the high cupolated effect. As the inferior cava dilates, the openings of the hepatic veins are pushed to the right and finally occupy the highest portion of the liver, which in Case 1 is the cupola of the right diaphragm.

Movements due to the dilatation of the heart, including the right heart in Case 1, are:

1. Descent of the sternum and ribs.
2. Descent of the heart and liver.
3. Apparent elevation of the right lobe of liver.
4. Displacement of the inferior cava to the right with convexity to the right.

In the fetus the following relationships are found:

1. Sternum high, ribs horizontal.
2. Right heart small.

3. Liver bilobed, two lobes of equal height.
4. Inferior cava near the median line with convexity to the left.

As development of the fetus to maturity advances the following changes are noted:

1. Descent of sternum, ribs in oblique position. The acquired descent of the ribs doubtless accounts in part for the apparent higher position (in terms of ribs) of the liver in adults as compared to the foetal position.
2. Descent of heart and liver.
3. Right heart enlarges.
4. Left lobe of liver atrophies and occupies a lower position, right lobe occupies a higher position.
5. Inferior cava moves to the right, becomes straight or slightly curved with convexity to right.

The movements described in pathologic dilatations of the right heart are similar in nature to the normal movements noted during development of the fetus to maturity. In fact, they seem to be a continuation of the same movement. Consequently it seems reasonable to state that as the right heart dilates the following changes occur:

1. The heart and liver are displaced downward.
2. The right lobe of the liver is elevated with respect to the left lobe, the ribs, and the right heart.
3. The inferior cava moves to the right, and its convexity to the right is increased.
4. The sternum and ribs are depressed. This depression of the ribs causes an apparent elevation of the right lobe of the liver, as high as fourth rib. This apparent elevation does not depend on the size of the liver.

In dilatation of the right heart the liver is actually depressed as measured by vertebræ, but apparently elevated as measured by ribs. As this changed relationship of the liver apparently depends on the same principles as the normal relationship of the liver, it is reasonable to assume that the apparent elevation (with respect to ribs) of the liver in dilatation of the right heart is constant; or a provisional general statement may be made, as follows: Dilatation of the right heart actually depresses the liver; the left lobe of the liver is depressed more than the right, producing a high cupolated right lobe; right lobe of liver due to depression of the ribs is higher than normal, apparent elevation; the degree of change in the form and position of the liver depends on the degree of dilatation of the right heart. Or the movement of the liver in markedly pathologic enlargement of the right heart seems to be a continuation of the normal movement occurring in the development of the fetus to maturity.

In pericarditis with effusion different physical forces are at work. Here the heart and venæ cavæ are compressed by the pericardial pressure and cannot dilate to the same degree as they do in the absence of pericardial pressure. The dilatation of the heart in pericarditis with effusion is most probably in many cases a post-mortem phenomenon, developing as the autopsy progresses, and due to the congestion of blood in the large veins and lungs flowing into the heart as the pericardial pressure is removed. To be sure, the myocarditis present in pericarditis favors dilatation, especially if the pericardial pressure is low owing to weak pericardial walls. Again, the heart may be dilated before the effusion developed. In general, the physical forces in pericarditis tend to keep the heart at the same size as it was when the effusion began to develop, or at a diminished size. The inferior cava remains in its normal position or may be pushed to the left by the descent of the liver. The dilating pericardium extends to the right over the

diaphragm a distance depending on the degree of dilatation and the intrapericardial pressure tends to push the liver down. The degree of displacement of the liver depends, of course, on the degree of pericardial pressure. Here the liver has only its normal support.

The inferior cava remains near the median line in a posterior position. Consequently the right lobe of the liver is deprived of the support rendered in Case 1. In pericarditis with effusion the right lobe of the liver is displaced downward approximately the same distance as the left lobe (without the apparent elevation as in cardiac dilatation). The right and left lobes of the liver are more nearly on a level or tend to assume the position found during fetal life. The sternum and ribs descend relatively the same distance as the liver. Here the liver is actually lower without the apparent elevation. A provisional general statement may be made as follows: Pericarditis with effusion tends to produce (or actually does produce) the following conditions: diminution in the size of the right heart; actual depression of the liver without apparent elevation of the right lobe so that the right and left lobes are more nearly in the same plane; displacement of the inferior cava to the left with its convexity to the left. Or, in pericarditis with effusion, the relationship of the right heart and liver tends to revert to that found in fetal life.

It is thus seen that in the two conditions diametrically opposite physical forces are at work, the cardiac dilatation tending to produce a relatively high position, the pericardial effusion, a low position of the right lobe of the liver. A difference of as much as two or more interspaces in the position of the right lobe of the liver may occur.

Naturally the variation in the position of the normal liver is of importance. In the literature reviewed it seems that much of the material on which present statistics of the normal position of the liver is based is pathologic, and that the subject needs reworking with the pathologic positions of the liver and the type of thorax constantly in mind.

In cardiac dilatation the root of the right lung remains at about its normal level as compared to the vertebral column, and in Case 1 was on the upper, posterior portion of the left auricular wall. When the right auricle dilated the lower anterior portion of the right lung was lifted upward, outward and backward. The downward displacement of the ribs without a corresponding downward displacement of the right lung gives an apparent elevation to the right lung. There is, then, an actual and an apparent elevation of the lower, anterior portion of the right lung.

In pericarditis with effusion, owing to the small left auricle, the root of the right lung is not displaced to a degree corresponding to that in dilatation. The lower, anterior portion of the right lung is not lifted as in dilatation, but pushed by the pericardial sac outward and backward. The downward displacement of the ribs gives an apparent elevation (if pleuræ are adherent the lung follows the ribs).

In cardiac dilatation the real elevation of the lower anterior portion of the lung border serves to diminish the area of lung-liver relative dulness. The degree of narrowing of this area varies from what might be called a diminished area to almost complete absence of relative dulness. The relative elevation of the liver places this area of dulness high, fourth rib.

In pericardial effusion the liver is pushed down proportionately more than the lower border of the lung is

elevated, so that the area of lung-liver relative dulness is narrowed or obliterated and occupies a lower position than it does in cardiac dilatation. If the pericardial pressure is sufficient to push the sternum and ribs down the liver is also pushed further down, and consequently does not alter the relationship as described. Or, the differential sign should be, in cardiac dilatation, a high liver with a diminished area of lung-liver relative dulness, fourth rib; in pericardial effusion, a low liver with a diminished area of lung-liver relative dulness, sixth rib.

The differential sign is composed of two factors, the position of the liver and the presence and position of a diminished area of lung-liver relative dulness. Of these the position of the liver is most important, for the reason that it is more easily detected in corpulent patients in whom the lung-liver relative dulness may be too narrow for detection. The position of the lung-liver relative dulness is more important than the fact that it is narrow. As the position of the relative dulness depends on the same forces which displace the liver the absence of or failure to find the relative dulness should not materially detract from the value of the sign. Owing to the physical forces causing the change in the lung-liver relative dulness this area must vary from a diminished area to an area of dulness too narrow for detection.

In cases of moderate cardiac dilatation and pericarditis with effusion the changes in the position of the liver and the lung-liver relative dulness cannot be developed to a degree sufficient for a clinical sign. But as the physical forces at play are essentially different in kind and effect these forces should develop in advanced cases a displacement of the liver sufficiently well marked to constitute a differential sign. As this sign becomes more and more marked as the lesions develop, it reaches its greatest development at a time when differential diagnosis is most difficult.

ABSTRACT OF DISCUSSION

DR. HAVEN EMERSON, New York: I believe that it is impossible to get the sign referred to with the patient in the dorsal position, or with the patient on his back on a table. In the dorsal position it is not possible to verify experimentally dilatation of the heart; but in the horizontal it is possible to verify by experimentation this condition in animals, the lower animals. What Dr. Calvert has presented to us should prove a very valuable diagnostic point if it could be verified by observation.

DR. W. J. CALVERT, Dallas, Texas: In the matter of experimental proof there are a number of difficulties to be considered. There is only one animal, so far as I know, having the same anatomic arrangement of the pericardium, namely, the monkey. Cardiac dilatation which causes a change in this relationship, it seems to me, must be slowly produced. There can be no question as to the sign that was produced; it was shown by cross section work on the cadaver, the section being treated with formol and reproduced. I have not had the opportunity to examine clinically many of these cases. I do not see how the position of such patients can materially influence the findings.

Leprosy in Colombia.—An article by Dr. F. Arteaga in the *Repertorio de Med. y Cir.* of Bogota states that out of the 3,031 lepers in institutions in the state of Colombia, 142 are between 3 and 9 years old; 1,265 other lepers live at home. The total for the country is thus 4,296 to a population of 4,303,000. He comments on the fact that cretins seem to escape leprosy, and suggests that possibly their serum might be utilized in serotherapy of leprosy.

NEURALGIAS AND FUNCTIONAL DISTURBANCES ARISING FROM INFECTIONS IN AND ABOUT THE TONSIL*

FRANK C. TODD, M.D.

Professor and Chief of Department of Diseases of Eye, Ear, Nose and Throat, University of Minnesota

MINNEAPOLIS

Disturbances now commonly attributed to infected tonsils may be grouped under three heads, as follows:

1. Acute and chronic tonsillitis (symptoms in the tonsils themselves).
2. Diseases of the contiguous mucous membrane, that is, pharynx, larynx, trachea, bronchi, Eustachian tube and middle ear, arising from the pouring out of infected secretion from the tonsillar crypts.
3. Remote secondary infections, such as rheumatic arthritis, pericarditis, etc.

To these three groups there should be added a fourth not commonly attributed to infected tonsils, but which, it is hoped, this paper will demonstrate should be so ascribed, namely:

4. Local infections involving structures in the neck contiguous to the tonsil, giving rise to symptoms in this region, presumably, through involvement of nerves, often; by direct irritation or inflammation, but, sometimes, through reflex involvement, resulting in neuralgias and functional disturbances.

1. The first group was, until a comparatively recent period, the only one recognized.

2. The part played by the tonsil, when diseased, in the production of inflammations in the contiguous mucous membrane of the pharynx, Eustachian tube and middle ear has for some years, however, been realized and, when these structures are found diseased, aurists and laryngologists carefully investigate the tonsil to determine its condition, commonly finding it at fault. Furthermore, the complete removal of such diseased tumors has resulted in the relief of many aural, pharyngeal, laryngeal and bronchial disturbances from the fact that these septic soaked sponges have ceased to create and supply the mucous membrane with their products.

3. That tonsils which have become diseased serve as portals of entry for infections which may be later carried to remote regions of the body, resulting in other foci of infection such as rheumatic arthritis, pericarditis, pulmonary tuberculosis, uveitis and various infectious diseases formerly not attributed to that long-misunderstood and supposedly useful organ, is now well proved and generally appreciated by the profession.

4. In addition to the second and third groups of diseases mentioned, both of which are secondary diseases, that is, those which might be called metastatic or general infections and those resulting from the actual pouring out of infections from the crypts on the surrounding mucous membrane, there is another group of cases (secondary infections also) attributable to tonsillar origin but not usually ascribed to this cause, or if so, only rarely or indefinitely so assigned. It is to this class of cases that I wish to call attention. Although the symptoms may vary widely and may apparently have no relation to one another, yet they should be grouped together, for they are but different symptoms of the same affection.

I refer to the structures contiguous to the tonsil which have become inflamed or infected or involved through pressure arising from the chronically diseased tonsil in

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

the substance of the neck (not to mucous membrane infections which have occurred from the pouring out of the infected material from the crypts, mentioned above) giving rise to certain definite local symptoms which may vary from an uncomfortable feeling or slight soreness felt by the patient below the ear and at the angle of the jaw, to a severe and recurrent neuralgia in the same region or running up to the ear or back of the ear, sometimes causing so much pain as to prevent sleep, or to loss of voice through involvement of or pressure on the superior laryngeal nerve which passes through this region external to the tonsil, or through involvement of the recurrent laryngeal, a branch of the vagus, which latter nerve also traverses this locality.

These symptoms may be attributable to the inflammation of the deep portions of the tonsil or to the structures contiguous to it or to a secondary infection of the lymphatic glands (so abundant in this region) into which the tonsillar glands drain. Many of these neuralgias occur as the result of pressure on or inflammation of the nerves passing through this locality, in which latter case the inflammation may become chronic, a true neuritis developing. Such would, likewise, be the case when attacks of hoarseness or loss of voice take place, despite the fact that no inflammation of the larynx is present, the function being disturbed because of involvement of the superior or recurrent laryngeal nerve.

It is obvious that the treatment of these chronic and recurrent attacks of neuralgias, etc., consists in the complete removal of these diseased tonsils even though there may be no history of acute tonsillitis or no apparent enlargement of the tonsils. Such treatment will usually reward the surgeon with prompt relief. It is equally obvious that in certain cases the symptoms may persist, owing to the continuance of the secondary inflammations either in the lymphatic glands or in the nerve. Even in such cases a gradual subsidence of the symptoms may be anticipated.

In the inspection of such tonsils it does not suffice to glance at them. The anterior pillar must be pushed back and the tonsil lifted from its bed by means of a blunt tonsil-hook, when it may be better examined. The exertion of traction on such tonsils with a hook, while causing no soreness or pain in the case of a healthy tonsil, will cause pain and flinching when it is diseased, or when the deeper structures are inflamed, and manifest soreness is a valuable guide in determining the cause of such symptoms. Frequently or usually, I have found in such cases, if the affection was one-sided, that such traction on the affected side would produce flinching, while on the unaffected side the patient would not complain.

The point about such symptom-complexes is that the patient and his physician do not attribute his trouble to his tonsil, even if the patient has been subject to acute tonsillitis. Usually, however, he is not so subject or has not been for some time, though in reality he may have a chronic low-grade of tonsillar inflammation present or only a chronic secondary inflammation in the contiguous glands or other structures of the neck.

In many of these cases the tonsil has been entirely overlooked because of the fact that the patient complains of little or no pain in the tonsil and, on simple inspection, there is nothing in the appearance of the tonsil to lead the examiner to suspect that here is the cause of the trouble. A study of the normal and pathologic tonsil with particular reference to the anatomy of the contiguous nervous and lymphatic system is neces-

sary to the proper understanding of these reflex phenomena which owe their existence to a diseased condition of the faucial tonsil.

Normally between the pillars of the fauces on either side there are from ten to eighteen compound follicular glands arranged in folds, leading into small recesses or crypts, or as many puncture-like orifices. Such normal tonsils are not in view unless the anterior faucial pillar is drawn away, and, even then, the space exposed shows no tumor or swelling, but only slight folds of mucous membrane, nor is there to be found any detritus, pus, or decaying particles of food in the retention pockets. When a tumor exists which may be firm and fibrous, or soft and made up partially of granulation tissue, or when this tonsil contains crypts filled with detritus, pus, cheesy particles, or decaying food, there is present a diseased tonsil. Such a diseased tonsil is what some laymen call "a tonsil;" when the normal condition exists, they say that there is no tonsil present. Many physicians have likewise fallen into the habit of designating loosely as "a tonsil" an abnormal or diseased structure.

The nerve-supply of the tonsil is derived from the glossopharyngeal and branches from Meckel's ganglion. The glossopharyngeal leaves the cranial cavity by way of the middle compartment of the jugular foramen, lying in advance of and a little internal to the pneumogastric and spinal accessory nerves. On the trunk of the nerve in the jugular foramen are two ganglia, an upper, the jugular, and a lower, the petrous. The former is inconstant and both are considered analogous to the ganglia on the posterior roots of the spinal nerves. At the petrous ganglion the glossopharyngeal nerve is connected with the pneumogastric and sympathetic nerves by communicating branches. The branches of the glossopharyngeal nerve, other than the terminal lingual, and communicating, are the meningeal, tympanic, carotid, pharyngeal, muscular and tonsillar. The tympanic branch arises from the petrous ganglion and passes to the inner wall of the tympanum. It ramifies on the promontory of the tympanum, forming the tympanic plexus which supplies branches to the round and oval windows and to the Eustachian tube and communicates with the carotid plexus and with the great and small superficial petrosal nerves. The pharyngeal branches join branches from the pneumogastric, superior laryngeal and sympathetic nerves and from the pharyngeal plexus which supplies the pharynx. The communicating branches arise from the petrous ganglion and run to the superior cervical ganglion, to the auricular branch of the pneumogastric, forming a loop; and one from the nerve just below the ganglion joins the lingual branch of the facial nerve. The tonsillar branches arise from under the hyoglossus muscle and are distributed to and around the tonsils, forming a plexus from which branches to the fauces and soft palate are derived.

Meckel's or the sphenopalatine ganglion is situated in the sphenomaxillary fossa below the superior maxillary nerve. Its sensory root is derived from the superior maxillary through the nomaxillary nerve. Its motor root is derived from the facial through the great superficial petrosal nerve which assists the great deep petrosal in forming the Vidian nerve. Its sympathetic root, the deep great petrosal nerve just mentioned, is derived from the carotid plexus. The motor and sympathetic roots enter the sphenomaxillary fossa as the Vidian nerve. Its branches are classified as the ascending, descending, internal and posterior.

The ascending or orbital branches pass through the sphenomaxillary fissure and pierce the inner wall of the orbit to supply the sphenoid sinus and posterior ethmoid cells. The descending or palatine branches are derived mainly from the sphenopalatine branches of the superior maxillary nerve. They are divided into anterior, external, and posterior palatine nerves. The anterior or large nerve passes down in the posterior palatine canal together with the posterior palatine artery and appears on the hard palate at the posterior palatine foramen. It runs forward in a groove on the under surface of the

hard palate and joins the terminal portion of the nasopalatine nerve. It supplies the gums and the mucoperiosteum of the hard palate. While in the posterior palatine canal, it gives off two branches (inferior nasal nerves) which pierce the vertical plate of the palate bone to supply the mucous membrane of the back part of the middle and inferior meatuses and the inferior turbinated bone. The external or middle palatine nerve descends in the external palatine canal to supply the tonsil and adjacent mucous membrane. The posterior palatine nerve descends in the accessory palatine canal to supply the tonsil, adjacent mucous membrane, levator palati and azygos uvulae muscles. With the external palatine nerve it joins a branch from the glossopharyngeal nerve to form the *circulus tonsillaris*, a plexus around the tonsil. The internal or nasal branches supply the mucous membrane of the septum and the posterior part of the middle and superior turbinated bones and of the posterior ethmoid cells and the antrum of Highmore. The posterior branch or pharyngeal nerve runs backward through the pterygopalatine canal and supplies the upper part of the pharynx and the eustachian tube.

The lymphatics of the tonsil, which are numerous, empty into the lymphatic glands near the angle of the lower jaw and into the deep cervical lymphatic glands. The glands near the angle of the jaw are part of the chain of superficial glands of the neck which lie beneath the superficial layer of the deep cervical fascia in the posterior triangle. The efferent vessels of these glands empty into the inferior deep cervical glands. The deep lymphatic glands of the neck number from twenty to thirty and are situated along the internal jugular and subclavian veins. They are divided into a superior and inferior set. The superior set is situated along the internal jugular vein between the base of the skull and the bifurcation of the common carotid artery. These glands receive the efferent vessels from the internal maxillary lymphatic glands and some from the submaxillary lymphatic glands, the lymphatic vessels from the cranial cavity, the deep muscles of the upper part of the neck, the posterior part of the tongue, the middle portion of the pharynx, the upper part of the larynx, and the upper part of the thyroid body. Their efferent vessels empty into the glands of the inferior set. The inferior set is situated along the internal jugular vein below the bifurcation of the common carotid artery and extends outward into the subclavian triangle along the subclavian vein. These glands receive the efferent vessels from the superior deep cervical and the superficial cervical glands; the lymphatic vessels from the lower part of the thyroid body, lower part of the larynx, lower part of the pharynx, upper part of the trachea and esophagus, and lower part of the neck, and some of the lymphatic vessels from the axillary and infraclavicular glands. Their efferent vessels unite to form the jugular lymphatic trunk, which empties into the right lymphatic duct on the right side and into the thoracic duct on the left side. The right lymphatic duct is a short trunk which empties into the subclavian vein or the internal jugular veins at the junction of these veins. Its orifice is guarded by a double valve. The thoracic duct receives the lymphatic vessels from about three-fourths of the body and empties into the left subclavian vein or the left internal jugular vein near the junction of these veins.¹

Having now briefly considered the tonsillar nerve-supply and communications and its lymphatic connections, what part should we expect the tonsil to play in producing functional disturbances and neuralgias in structures, the nerves of which become involved by inflammation or pressure?

Direct and reflex pain may arise from an infected tonsil. This pain may be referred to the side of the face and ear, the patient complaining of soreness and discomfort in this region. This can be explained by the patient's reference of irritation to the superior maxillary and auricular branch of the pneumogastric which supply the face and external portions of the ear. Deep-seated pain in the ear may be caused by irritation of the tympanic branch of the glossopharyngeal.

Through the tonsillar lymphatic system, inflammation of glands or other structures in the neighborhood of the tonsil may likewise give rise to pain, direct or reflex, and soreness through involvement of nerves contiguous to these secondary glands, and pain may occur in the nose, teeth, gums, hard palate, or antrum of Highmore, sphenoid, ethmoid orbit, pharynx, larynx or trachea.

A peculiar hacking cough (which may be called a reflex tonsil cough) without expectoration is also a symptom of irritation of the superior laryngeal nerve because of an enlargement of lymphatic glands of the neck brought about in the same manner as it is evinced by an enlarged thyroid gland or aneurysm of the internal or external carotid artery.

Pressure on the superior laryngeal nerve by the tonsil or by secondary swelling of glands or other structures in this locality may cause, not alone cough, but recurrent momentary attacks of cessation of respiration and also expulsion of food. As the internal branch supplies the cricothyroid muscle, the contraction of which stretches the cords, paralysis of this nerve causes hoarseness or partial loss of voice.

The inferior deep cervical glands drain the superficial cervical glands into which the tonsil feeds. An infection of one of these deep lymphatic glands may involve the recurrent laryngeal, the motor nerve that supplies all the intrinsic muscles of the larynx except the cricothyroid. Moderate pressure on this nerve causes spasm of the muscles of the same side of the larynx, resulting in dyspnea and change of voice; greater pressure causes paralysis and alteration of the voice. Other disturbances which may result are defects of hearing, tinnitus aurium, and anesthesia of the pharynx and larynx, resulting in an entrance of food into the trachea with consequent choking or difficult swallowing.

The presumption is reasonable that involvement of the pneumogastric nerve by pressure or otherwise may give rise to disturbed digestion, and the relief which follows the removal of diseased or enlarged tonsils is more likely due to this fact than because of ingestion of septic material from the tonsils, the stomach readily disposing of such material without detriment to its function. Likewise, cardiac action may be disturbed, palpitation resulting.

The report of cases which are examples of the various phenomena here suggested could be appended, but would only serve to reiterate what has already been said. The careful observer who analyses the nervous anatomy in the region of the tonsil and the lymphatic glands draining the tonsil will be able to judge as to when he may attribute to the tonsil the various diseases, functional disturbances and neuralgias, which may arise from tonsillar infection.

CONCLUSION

In conclusion I wish to emphasize the following points:

1. Pain and soreness in the neck in the region of the tonsils usually arise from diseased tonsils.
2. Neuralgias in the region of the tonsil, ear, side of head, neck, nose, teeth, gums, or antrum of Highmore, may be and frequently are caused by diseased tonsils.
3. Disturbances of function through pressure on or inflammation of nerves may manifest itself in hoarseness, in loss of voice, cough, difficult deglutition, or entrance of food into trachea, with regurgitation, or in defects in hearing, dyspepsia and disturbed heart action.
4. Such diseased tonsils may not be and usually are not large or acutely inflamed. They must be carefully

1. Deaver: *Surgical Anatomy of the Head and Neck*, 1907.

examined by the surgeon who should pull them into view with a dull hook, determine whether the crypts contain detritus, whether the tonsils are sore to such manipulation, bleed easily, or otherwise give evidence of being diseased.

5. Such tonsils should be carefully and completely removed.

6. Relief of secondary infections usually follows immediately on removal, but, sometimes, only slowly, if neuritis or secondary glandular involvement is present.

7. In certain cases paralysis may be permanent.

506 Donaldson Building.

ABSTRACT OF DISCUSSION

DR. LAFAYETTE PAGE, Indianapolis: Many minor disturbances not generally recognized are due to diseased tonsils. These nervous disturbances about the throat and base of the skull, such as mastoid and occipital neuralgias, functional disturbances of the facial and other nerves emerging from the base of the skull, are often cured by removing the tonsils. A neurologist referred a case to me a year ago in which he thought there might be something in the condition of the tonsils producing functional paralysis of the facial nerve. There was nothing in the superficial appearance of the tonsil to indicate disease except slight enlargement. The tonsils were removed and I found deep down in the structure of the right tonsil a large cystic abscess. The nerve soon regained its function and there was no after occurrence of the paralysis. Whether this was due to pressure from enlarged glands or septic absorption it is difficult to say. Dr. Todd mentioned spasm of the glottis as not an uncommon reflex disturbance resulting from diseased tonsils, and I can recall a number of most persistent cases of this affection and among them two very distressing cases which were relieved by removal of diseased tonsils. In one of the patients the spasms came on at 2 or 3 o'clock in the morning, after a few hours' sleep, and often persisted until the patient became unconscious from suffocation. I am convinced that the tonsillar tissues are the most frequent cause of reflex spasms of the larynx. Many of the minor disturbances of the throat like laryngeal cough, constant desire to clear the throat, pharyngeal irritation, submaxillary pains and general discomfort of the throat are of tonsillar origin and are apt to be overlooked when the tonsils present no superficial evidence of disease. These are the patients who consume large quantities of throat lozenges and are liberal patrons of "patent medicines." As a prophylactic measure I think we make no mistake in removing the tonsils in our efforts to relieve this class of minor ailments.

DR. F. E. AUTEN, Belleville, Ill.: I had two cases of facial neuralgia that cleared up after removal of the tonsils which I believe were due to septic absorption. There is an individual in Belleville today that has had neuralgia for four years and the tonsils are very sensitive, but who refuses to have them taken out because her physician has told her that they were put there by God and should not be removed. I am satisfied that there is a most urgent need for investigation along this line and that it will pay us to give a good deal of attention to these neuralgias of the face and head.

DR. JOHN D. MACLAREN, Norman, Okla.: What was the condition of the sinuses of the cranial and facial bones in these cases? Dr. Killian has shown that sinusitis may produce the same symptoms as the ones of which the essayist speaks. Have there been any investigations which show that the faucial tonsil does drain into any other part of the lymphatic system? The peritonsillar tissue is thus drained.

DR. C. F. WELTY, San Francisco: I have had several of these cases of pain about the ear and in one case that I know of a mastoid operation was done though the pain was afterward relieved by enucleation of the tonsils. I want to make a suggestion in relation to this hoarseness. I would offer another solution of that; we know that in diseased tonsils there is a certain amount of mucus and mucopus, dropping into the pharynx and larynx all the time (another indication

for the tonsil operation) particularly in singers, who are not able to hold notes; this is because of the deposit of a particle of mucus on the cords, in other words they have unreliable voices.

DR. H. B. LEMERE, Omaha: A method of examination and treatment of these tonsils that has proved good in my experience, is the use of the Bier cups. The ordinary bulb provided with the instrument is not strong enough to draw out the concretions from the tonsils and I have used the suction produced by air pressure and the large bulb provided by the manufacturers. One treatment will not always relieve the condition. It is often necessary to use massage, which is very well borne by these patients. In many instances I have examined the tonsils without discovering anything at all and then with the suction apparatus I have drawn out large concretions. The method is efficient with highly nervous patients who will not submit to operation, though the treatment may have to be continued for some length of time. In some of these cases, after using suction, there is spasmodic contraction of the glottis, so that this condition should not always be ascribed to reflex action. In many of these patients the teeth and gums are at fault rather than the tonsils, and the tonsils may be infected from this source. The headaches, I think, are more apt to be due to disease of the nasal accessory cavities, therefore I do not think we should cut out the tonsils in every instance, but we should try to discover the primary infection which is not always in these organs.

DR. GEORGE F. COTT, Buffalo: In nine out of ten of these cases when there is pain in the head and face there is disease in the nasal accessory sinuses. If it is not found there it will probably be found in the tonsils.

DR. FRANK C. TODD, Minneapolis. The sinuses are of course responsible for many similar conditions. I did not mean to be understood as saying that all such symptoms are due to the tonsils but that the tonsils would produce such symptoms, and that we less frequently ascribe them to the tonsils than we should. For instance, for many years we have known that facial paralysis and other involvement of the nerves are due to enlarged thyroid gland, we have not ascribed them so much to enlarged tonsils.

POISONING FROM BITES OF COPPERHEAD SNAKES (*ANCISTRODON CONTORTRIX*)

PRENTISS WILLSON, M.D.
WASHINGTON, D. C.

Recently, through the courtesy of Dr. George Tully Vaughan, I saw in a ward of the Georgetown University Hospital the following case of poisoning from the bite of a copperhead:

The patient, a boy aged 13, had been playing under a bridge, and on reaching up to one of the timber supports felt a sharp stinging pain in the index finger of his left hand. No snake was seen. The hand began to swell rapidly and the boy hastened home and was then taken to see a physician, who diagnosed the case as one of snake-bite, placed a ligature around the forearm and finger, and advised that the boy be hurried to a hospital in Washington. This was done and the boy reached Washington from an adjoining state late in the afternoon of the day on which the injury was received. At this time the child was in a condition of considerable shock, in the causation of which the pain of the ligatures and fright probably played a considerable part. The pulse was slow and of low tension. The hand and arm were much swollen and somewhat discolored. The interns who received the patient very promptly instituted the accepted treatment for such cases, namely, a free incision reaching to the bone the whole length of the finger, the application of potassium permanganate crystals to the wound so made, and liberal stimulation with strychnin by hypodermic—everything, of course, under the usual aseptic precautions. The incision disclosed a certain amount of effused blood in the bitten finger and there were a few ecchymotic discolorations of the hand. A urinary-

sis made the day following the injury showed nothing abnormal—no albumin, blood, or blood-pigment present. The swelling rapidly began to disappear and the patient left the hospital in a few days with the wound in the finger healthy and healing by granulation. There can be no doubt that this was a case of snake-poisoning and due to the bite of a copperhead, since this is the only venomous species found in the District of Columbia or its immediate vicinity.

I have recently reported¹ another case of snake-bite due to the copperhead. This accident also occurred under a bridge. The reptile, a small copperhead, being mistaken for the common milk snake, *Ophibolus dolatus*, was carelessly picked up and inflicted a bite on the index finger. The patient was a man. There was no constitutional disturbance in this case and locally only swelling as far as the elbow with slight pain and a slight ecchymotic discoloration of the bitten finger. The day following, almost twenty-four hours after the injury and before being seen by me, the finger was incised and potassium permanganate applied. The wound so made suppurated and healed slowly by granulation.

Some few years ago I saw a patient who had been bitten on a finger by a copperhead while lifting a stone under which the reptile was concealed. Before coming under my observation the wound had been incised and treated by constant applications of a strong phenol solution. When first seen the man was in imminent danger of phenol gangrene of the bitten finger. As far as the effects of the venom were concerned, the arm was considerably swollen and mottled with ecchymotic discolorations extending to the shoulder. In this case also the constitutional disturbance had been of the most trivial character.

In a recent article² I have collected a series of 740 cases of poisoning from the bites of snakes indigenous to the United States. Of 566 cases in this series, in which the species of the snake causing the injury was definitely known, 97 cases, or 17 per cent., were due to the copperhead. The third of the cases mentioned above is included in these statistics, but the other two cases are not, making a total of 99 cases to be considered here. In these 99 cases there were 5 fatalities, a mortality rate of about 5 per cent.

Two fatal cases were reported by Kunkler.^{3, 4} Of these the first³ was in a boy aged 9, who received no treatment. This case is reported so very briefly that it is of little value. The second⁴ was in a boy of 6, bitten on the little toe. Death ensued on the fourth day. The local symptoms in the case were: On the first day, rapid swelling. On the second day the entire limb was swollen, the foot a shapeless mass, large vesicles over entire limb, and the course of lymphatics indicated by red lines. On the third day there was gangrene of the entire foot, extending rapidly, inflammation extending over groin and scrotum. The constitutional symptoms were, on the first day, nausea, cold skin, rigors, feeble pulse; second day, high fever, rigors, constant delirium, tongue dry and red, diarrhea; third day, condition worse, delirium continued; fourth day, convulsions and death. The treatment in this case consisted in free incision, labial suction, injections of a solution of iodine and potassium iodid locally, with ammonia and opium by mouth. It is perfectly obvious that death in this case was not due at all to the primary effects of the

venom, but to an engrafted septic process of severe grade. The etiologic significance of incision and labial suction on this septic process is, of course, problematic.

The three remaining fatalities in the series of 99 cases were reported to me in personal communications from Crum of Brunswick, Md., and Turner of Bluemont, Va. These physicians had not treated the cases, but knew of them and believed them to be authentic. They also expressed the opinion that the fatal result was due largely to the large amount of bad whisky consumed, and in one case, at least, to a marked condition of chronic alcoholism.

In regard to the absolute frequency of poisoning from the bite of the copperhead little that is definite can be said. Certainly the fact that I, with no special effort on my part and practicing in a large city, have seen three cases and know of two others having occurred recently in the immediate vicinity, would indicate that the condition cannot be so very rare. This reptile is widely distributed east of the Mississippi as far north as Massachusetts and possibly even Vermont. According to Stejneger,⁵ Kansas, Oklahoma and Texas seem to mark the western extent of its range, and it seems to be absent from the peninsular portion of Florida. In many localities where the rattlesnakes have been completely exterminated the copperhead is still found in considerable numbers. In regard to the relative frequency of bites by this species, there can be no doubt that, as stated in my first paper,² for reasons there presented, the figure of 17.1 per cent. as representing the proportion of cases due to the copperhead in 566 American cases (including the rattlesnakes, the copperhead, the water moccasin and coral snakes) is entirely too low.

The attitude of the profession regarding the danger from all cases of snake poisoning in this country is sadly in need of revision. The bites of the larger species of rattlesnakes and of the water moccasin are very dangerous, but fortunately they are comparatively rare. The danger from bites by the smaller rattlers and the copperhead is certainly slight. This being true, it is very important to see that the treatment is not only necessary but that it is not positively harmful. In the 99 cases considered only one of the 5 fatalities can be properly attributed to the direct activity of the venom. One of the other fatal cases was undoubtedly due to a septic infection to which the treatment of the injury predisposed. In the remaining three cases the alcoholic intoxication, added to the venom intoxication, undoubtedly contributed to the result. Thus a corrected mortality in these cases would be about 1 per cent., certainly small enough to indicate the slight danger to life from the venom itself. As far as the harmfulness of the accepted treatment is concerned, the three cases mentioned at the beginning of this paper may well be considered in evidence. In the first case the parents were forced to take the child on an expensive and entirely unnecessary journey. The finger was then unnecessarily opened. Such incisions are not without danger of subsequent deformity. In the second case again the finger was incised without reason, with a resulting infection which might have been serious. In the third case another finger was unnecessarily opened and nearly lost as a result of phenol gangrene. My conclusion from all this is that in poisoning from the bites of copperheads we have a condition of no great rarity in the eastern states, the danger from which is

4. Kunkler: Cincinnati Lancet and Observer, 1859, new series, ii, 662.

5. Stejneger: The Poisonous Snakes of the United States, Report of U. S. Nat. Museum, 1893, Washington, 1895, p. 337.

greatly overestimated by both laity and profession; that the local treatment is unnecessarily severe and dangerous, in that it opens up, often without due regard to asepsis, tissues which are predisposed to septic infection and tends toward producing subsequent deformity. In other words, in these cases, as usually treated, we have a condition the treatment of which is worse than the disease.

Locally the ideal treatment consists in the application of a series of ligatures between the wound and the heart, tied tightly enough to impede the return flow of blood and lymph but not to cut off the circulation and obliterate the pulse. This procedure makes the absorption of venom slower and therefore less likely to overpower the resistance of the body to the poisoning. When first seen in many cases the extremity will be ligated tightly enough to cut off the circulation completely. These ligatures should be promptly relaxed, as gangrene has occurred under these circumstances. I am fully convinced that the best interest of the patients in the majority of these cases of copperhead poisoning will be best conserved by no interference with the wound beyond the application of an antiseptic occlusive dressing. In cases in which a young child has been bitten by a large snake and comes under treatment at once, dissection of the wound and the use of crystals of potassium permanganate under every aseptic precaution would, of course, be indicated. When the case is seen after the lapse of some time, with the venom in all probability well diffused through the tissues, I doubt if this treatment does any good even in such cases, and certainly not enough to compensate for the increased danger of ordinary septic infection.

The general treatment is simple but important. The copperhead venom produces a very marked fall in blood-pressure and exerts a selective depressing effect on the respiratory center. The low blood-pressure should be treated by the administration of adrenalin by intravenous injection, if the condition promises to be at all serious. Of course, in such cases as the second and third reported above such a procedure would be highly unnecessary. Strychnin is probably as likely to be useful as any other stimulant, especially in those cases where there is a tendency toward respiratory depression. Caffein and camphorated oil would seem to be indicated on theoretical grounds, in bad cases, as in young children. The recumbent posture with the head low and external heat should be used. Bandaging the extremities, abdominal compression by a tight binder, and artificial respiration may be tried in very serious cases, but such cases will be very rare except in young children.

In conclusion I should like to urge on the members of the profession who have the opportunity of seeing these cases of copperhead bite, that they should be reported. Most of them seem like very trivial affairs, but it is for this very reason, in order to impress this fact on the profession, that they should be reported to the journals.

The Spinal Sign of Serofibrinous Pleurisy.—F. Ramond found the iliocostal and longissimus dorsi muscles constantly enlarged on the side corresponding to the pleural lesion in 76 cases of primary pleurisy and in 18 out of 24 secondary cases. The muscles below the twelfth rib can be felt much larger and more elastic on this side than on the other as the patient bends forward or to the side and the groove at the side of the spine is palpated. His communication on the subject was published in the *Bull. de la Soc. méd. des hôp.*, 1910, xxvii, 747.

ENDONASAL METHOD OF REMOVAL OF HYPOPHYSEAL TUMORS

WITH REPORT OF TWO SUCCESSFUL CASES

DR. OSKAR HIRSCH
VIENNA

In his article on the surgery of the hypophysis from the standpoint of the rhinologist, Dr. J. M. West¹ mentioned the fact that "heretofore rhinologists have been interested in the hypophysis only in a general way." Later on in his article he describes a method by which he resects the septum endonasally, thereby reaching the sphenoid, which he opens widely, and through this opening reaches the hypophysis.

Although Dr. West searched the German literature with great care concerning the operative treatment of hypophysis tumors, he neglected those publications which described the endonasal method, which was the most important to him.

In March, 1909, I published a new method² of endonasal operation for the removal of hypophyseal tumors. This method is based on Hajek's³ radical operation on the sphenoid sinus and is done in several sittings. It is performed in the following way:

Operation.—Under cocain anesthesia the middle turbinate is removed at the first sitting. After a few days, again under cocain anesthesia the anterior and posterior ethmoidal cells are removed, by which operative procedure the entire anterior wall of the sphenoidal cavity is exposed. After another interval of several days, again under cocain anesthesia, the anterior wall of the sphenoid is removed *in toto*. Here one may again wait several days before beginning the last step of the operation, or as desired, may continue with the opening of the hypophyseal prominence and partially remove the hypophysis.

This is the method I demonstrated on the cadaver at the meeting of the Gesellschaft der Aerzte in Wien in March, 1909.⁴

In my first publication, and also in my demonstration, I gave reasons why my method, done under local anesthesia, should supersede the method of Schloffer.⁵ My arguments in short are the following:

1. By the method of Schloffer it was impossible up to that time to remove the tumor of the hypophysis completely.

2. The removal of small portions of the tumor has been enough to influence the course of the disease favorably.

3. By my method it is possible to remove the tumor partially and so to get equally as good a result as one gets by the major surgical procedure of Schloffer.

My suggestion was taken skeptically. In the following year I had no opportunity of demonstrating the feasibility of my method on the living. But through the courtesy of Hofrat v. Wagner it was first possible for me to operate by my method on a patient suffering from tumor of the hypophysis and thus give my proposal a practical value.

History.—The patient was a woman aged 35, from Hofrat v. Wagner's clinic, who for seven years had epileptoid attacks, and for one year suffered from unbearable headaches and disturbances of sight. The Roentgen examination, made by Doctor Dr. Schüller, showed an enlargement of the sella turcica.

and an erosion of the clinoid processes, which confirmed the diagnosis of a hypophysis tumor. Inasmuch as, through the pressure of the tumor on the optic nerve, the left eye was blind and the right eye was in imminent danger of becoming so, the proposal to remove the tumor was made and accepted by the patient.

Operation.—With permission of Hofrat v. Wagner I used in this case the method of operation published by me in 1909.² The operation was done under cocaine anesthesia endonasally and in several sittings. The course of the operation in this patient was as follows: In the first sitting I removed, under cocaine anesthesia, the middle turbinate of the left side, which is an insignificant procedure. After several days in a second sitting I removed the ethmoid cells. This operation was also done under cocaine anesthesia without any hemorrhage worthy of mention. After a several days' pause I resected in a third sitting the anterior wall of the sphenoidal cavity, again under a local anesthetic without pain or hemorrhage. After this operation the hypophyseal prominence, reaching deep into the sphenoidal cavity, was visible. The previously described procedures are commonly used by rhinologists in the treatment of chronic empyema of the sphenoidal sinus. The new feature in my method is the opening of the hypophyseal prominence with a chisel and the exposure of the tumor. For this operation I also chose local anesthesia. After cocaineizing the nose and sphenoidal sinus with a 20 per cent. cocaine solution I placed on the hypophyseal prominence a small chisel and by careful hammering made a transverse fissure in the bony envelope of the hypophysis tumor. Into this fissure I placed an elevator that is made in the form of a right angle and broke away the bony covering of the hypophyseal prominence in a rather large area. Through this opening in the bone the bluish dura became visible. Although this operation was done without hemorrhage or pain, I did not continue, as I wanted to see if this opening would not suffice to relieve the disturbances caused by the pressure of the tumor. This expectation was not realized and after several days it became necessary to lay bare the tumor itself.

I again cocaineized the nose and the sphenoidal cavity with a 20 per cent. cocaine solution and epinephrin and soon found the opening I had made in the hypophyseal prominence and with a knife opened the dura along the sphenoidal septum and pulled it away laterally as a flap. Immediately the gray hypophysis tumor arched through the opening into the sphenoidal cavity. I cut into the tumor with a knife and immediately a blood-tinged fluid ran from the nose and mouth. As I again examined the tumor it was smaller and pulsated at the wound margins, between which, on probing, I came into a cavity. I removed a small piece of the cyst wall and did not tampon, but merely placed a small ball of cotton in the anterior nares of the operated side of the nose.

Subsequent Course.—Immediately following the operation the patient's head felt much relieved. She was so slightly disturbed by the operation that she was able to walk with a nurse from the operating room to her ward. Her condition following the operation of March 8, 1910, remained good. She enjoys the best of health, is entirely free from headache and her temperature was always normal. The vision of the right eye improved in two days following the operation from 1/30 to 4/30, and two weeks later was 9/60; at the time of writing this paper her vision was 6/10. The field of vision also has improved greatly; the left eye remains amaurotic.

Examination of Specimen.—The microscopic examination of the excised cyst wall (Dr. Erdheim) showed hypophysis tissue; of tumor tissue there was nothing to be seen. The examination of the cyst contents showed phagocytic elements and blood pigment, a sign of an old hemorrhage.

The treatment of the above-mentioned case took more than five weeks. If one subtracts a longer pause, which was made in order to have some new instruments constructed, and if in the future one does several stages of the operations in one sitting, there will still remain two to three weeks as the necessary time to complete the treatment of a case.

As it may be possible that the progressive symptoms of a case, especially the optic atrophy, will not allow so long a period of treatment, I searched for a method in which the operation of hypophysis tumor could be performed at one sitting.

Influenced by Kocher's³ operation, I made experiments on the cadaver to show that one could open endonasally both sphenoidal cavities and the hypophyseal prominence under local anesthesia in one sitting and reduce the danger of infection to a minimum.

This method which I will describe later is a continuation of Killian's⁴ submucous window-resection of the nasal septum, but includes the resection of the rostrum sphenoidale; also the anterior wall of both sphenoidal cavities and of the sphenoidal septum, by which the hypophyseal prominence is exposed in a satisfactory manner. The technic of this method in practice would be the following:

The mucous membrane of both sides of the nasal septum is cocaineized with a 20 per cent. cocaine solution and infiltrated in its entire extent with Schleich solution. An incision is now made along the anterior edge of the quadrangular cartilage, through the mucous membrane of one side, down to the cartilage, and the mucous membrane is raised by means of a raspatorium, together with perichondrium and periosteum, from the cartilage and bone. The cartilage is now incised $\frac{1}{2}$ cm. from the original incision and a raspatorium slipped between the perichondrium and the cartilage and carried to the posterior border of the septum; the mucous membrane, together with perichondrium and periosteum, are now raised from cartilage and bone on this side. The membranes are now held apart by a nasal speculum and in this way a medial nasal cavity formed in which one sees the bare cartilage. This is removed with one sweep of the cartilage knife and the vomer and the perpendicular plate of the ethmoid are resected with the aid of a bone forceps. Up to the present this operation is identical with Killian's submucous septum-resection.

To bare the anterior wall of the sphenoidal cavity it is necessary that the mucous membrane of the vomer where it joins the sphenoid be also separated from the bone. This is very easily done, after which the mucous membrane is separated from the anterior surface of the sphenoid on both sides as far as the ostium sphenoidale, so that the raspatorium falls into the sphenoidal cavity. Now, through this sack of mucous membrane one removes posterior part of the vomer and the rostrum sphenoidale with the bone forceps, and with several strokes of a chisel one breaks through the anterior wall of the sphenoid cavity and after removing the sphenoidal septum one sees the hypophyseal prominence in its entirety.

After opening the sella turcica and the dura of the hypophysis, respectively, the hypophyseal tumor lies free in the sphenoidal cavity.

By using this method I have opened the sella turcica on a cadaver whose skull had not been previously opened. Dr. Erdheim, an assistant at the Vienna Pathologic-Anatomic Institute, was kind enough to dissect the skull and found that by using the above-mentioned method I had made a large opening in the floor of the sella turcica without having injured any of the important neighboring organs (optic nerve, cavernous sinus, etc.)

Should the middle turbinate extend too far into the nose so that the mucous membrane of the septum cannot be separated from it far enough, they must be removed several days before beginning the real hypophysis operation.

Some time ago I operated in a case of hypophyseal tumor by the last-mentioned method (submucous-resection of the septum of the nose and of the sphenoidal cavities). Up to the present time the patient's general condition is good and she is without fever.

daily subjected to pressure. What surgeon of experience but has seen many cases of carcinoma or sarcoma commence in warts, moles, eczematous patches and fissures? It is my firm conviction that by timely surgery cancer could be prevented in a large percentage of cases. Most of the cases of cancer cured by surgery are those which are cured before they come, plus those which are cured before the diagnosis can be made save by the microscope; and herein lies the cause of cancer quacks' continued popularity: "Didn't he cure Belinda Brown of a cancer which commenced just like that one which killed Sarah Smith?" The point I wish to make is this: that by removing causes of irritation in the shape of gastric ulcers, lacerated cervixes, phimoses, gall-stones, kidney-stones, warts, moles and other non-malignant tumors and causes of irritation, surgery can prevent more deaths from cancer than it can by the removal of cancerous conditions after such a diagnosis is possible. I venture to suggest here an addition to our cancer vocabulary, viz., potential cancer. Through a personal communication from Dr. H. K. Mouser⁵ I learned that of the epileptics in the Indiana School for Feeble-Minded Youth 17.64 per cent. have a history of difficult labor, and that of all the inmates the percentage of difficult labor in 727 cases in which the birth history is given is 11.69. Practically all children who suffer from cerebral hemorrhage produced by birth injuries are permanently disabled, and 30 per cent. of those who recover develop epilepsy.⁶ Ten per cent. of the cases of infantile convulsions and practically all cases of congenital palsy are due to abnormal labor.

What does "abnormal" and "difficult" labor mean in these instances? It means version, high forceps, and labor terminated by the unaided forces of Nature after an unconscionable lapse of time and expenditure of maternal energy. In these so-called abnormal labors the maternal mortality is 1.14 per cent., the maternal morbidity is 42 per cent.; over 20 per cent. of the children die,⁷ and 10 per cent. of those that live are seriously injured as a result of birth injuries.⁸ Couple these facts with those just given concerning fetal morbidity in this class of labors, and see if you do not agree with me in the assertion that timely, courageous and intelligent obstetric surgery can prevent much of this morbidity and mortality. Some experience and a careful study of the subject forces me to the conclusion that Cesarean section in competent hands could prevent much of this loss of life and usefulness.

In the preparation of a paper on Cesarean section for the Southern Surgical and Gynecological Association⁹ I gathered through correspondence the opinions of a number of men of experience on this subject. Permit me to quote four, which fairly represent the concensus of opinion of the whole.

Newell of Boston says:

In the first place, the elective operation done before labor, in the absence of complicating disease, with the patient in good condition, is, in competent hands, a safe surgical procedure, and I believe the morbidity in these cases is very slight and certainly very much less than could be claimed for the ordinary obstetrical operation in the same class.

De Lee thinks that "Cesarean section ought to have a wider field and should replace many of the brutal forceps and version operations." Davis says:

Elective Cesarean section by competent operators, on uninjured and uninfected patients in good condition, gives at the present time the best chance of life and health to the mother and child in cases where mechanical disproportion or physiologic incompetence to endure labor are markedly present.

Hirst (who has done 80 Cesarean sections, with 5 deaths) says:

My recent experience convinces me that Cesarean sections may be done with impunity after hours of labor, if the woman is not infected and the technic of the operation is as good as it ought to be; the mortality even in infected cases need not necessarily be excessively high.

That prompt surgical treatment in birth injuries will prevent many deaths, and much invalidism, most of which is worse than death, no one who has studied the subject will deny.

As intimated in the beginning, this paper can be little more than suggestive, but if it is instrumental in arousing an interest in the subject commensurate with its importance, then my object has been accomplished.

West Wayne Street.

A CUTANEOUS ANAPHYLACTIC REACTION AS A CONTRA-INDICATION TO THE ADMINISTRATION OF ANTITOXIN *

W. L. MOSS, M.D.

Associate in Medicine, Johns Hopkins University

BALTIMORE

Almost every physician who frequently has occasion to administer antitoxic serum has seen more or less serious symptoms follow the injection in individuals who months or even years previously have received serum. These symptoms usually develop within twenty-four hours, often in less time, and may be slight, consisting of one or several of the following: erythema, urticaria, swelling of lymph-glands, joint pains, fever, or they may be very grave, consisting of the above in an exaggerated form with profound collapse, albuminuria and bloody stools.

It seems very desirable to be able to determine in advance those cases in which a second administration of serum will precipitate dangerous anaphylactic manifestations. In a recent paper Knox, Moss and Brown¹ described a local cutaneous anaphylactic reaction which indicates hypersensitiveness in rabbits to horse serum. Thinking that this test might give the desired information in the case of patients requiring a second injection of antitoxin after a lapse of sufficient time for the development of hypersensitiveness, I have applied it in thirty cases.

Before discussing the results, the test, which is extremely simple and easy to perform, may be described as follows: The skin of the non-hairy, inner side of the upper arm is cleansed with alcohol, dried with a sterile sponge and 0.01 c.c. normal horse-serum, preserved with a few drops of chloroform, is injected intradermally. A fine needle and a hypodermic syringe divided into hundredths of a cubic centimeter is convenient for this purpose, and undiluted serum should be used. A positive reaction consists usually of an area of inflammation

1 to 2 cm. in diameter, which comes on within twenty-four hours and disappears in two or three days. It sometimes happens that the entire reaction is over in twenty-four hours, so that an observation should be made at the end of about ten hours after the injection. The reaction is purely local at the site of injection and in no case have any constitutional symptoms or discomfort resulted. With a negative reaction nothing is to be observed except perhaps the needle-prick, and if care be taken to introduce the needle sufficiently superficially even this may not be found.

Of the thirty individuals tested nine had never received any form of antitoxin and all nine gave a negative reaction. The remaining twenty-one individuals had received antitoxin from four months to ten years previously. Ten of these gave positive reactions and eleven negative. The result does not seem to depend on the length of time which has elapsed since the injection of antitoxin, as the positive and negative reactions were about equally distributed as regards the time interval since injection. It is hardly to be expected that all ten of the patients giving a positive skin reaction would develop serious anaphylactic symptoms should they receive another therapeutic or prophylactic dose of antitoxin, but of the ten positive reactions especial attention must be called to three which differed markedly from the remainder. These set in with explosive suddenness, one at the end of about six hours, another after about eight hours and the third after about twenty-four hours. Immediately surrounding the site of injection there suddenly appeared an urticarial wheal about 1.5 cm. in diameter and surrounding this an areola of inflammation about 5 to 6 cm. in diameter. The appearance of the reaction was accompanied by marked itching, but no other manifestation. These three reactions subsided as the others did, except, perhaps, in less time. It would seem that reactions of the nature just described might indicate danger from any further injection of antitoxic serum.

The value of this test can be determined only by injecting therapeutic or prophylactic doses of antitoxin in individuals who give a positive skin reaction. Since the value is undetermined, patients who give a positive skin reaction must present themselves in whom the indication for the administration of antitoxin is sufficiently urgent to overbalance any possible fears we may have of serious anaphylactic manifestations resulting.

I have presented this reaction before having tested it out fully, because of the length of time which would be required to do it in this hospital, owing to the fact that at present we have no ward for contagious diseases such as diphtheria. I would suggest that wherever a delay of twenty-four hours is permissible before the injection of antitoxin, this test be performed; if the patient gives the ordinary positive reaction and the indication for antitoxin is very slight it might be safer to withhold the antitoxin, but if the indication is fairly strong the patient should receive the injection. In the presence of a positive reaction, such as described in the three cases above, I should hesitate to give antitoxin except on very urgent indications; however, the value of the test must be finally determined by just such cases, and it is to be hoped that any who carry out the test will report the results in order that we may determine if the reaction gives us a means of knowing in advance those cases in which second injections of antitoxin are contraindicated

and thereby prevent the lamentable accidents which sometimes now occur.

In conclusion I would say that, so far as I am aware, no such test as I have proposed has been recorded, although I make no claims to having gone through the enormous literature which has appeared in the last few years on the subject of anaphylaxis.

LARGE ACCIDENTAL VULVAR HEMATOMA AT TERM

COLIN G. ROBERTSON, M.D.
SANDUSKY, MICH.

Accident.—On July 4, Mrs. A. R., aged 39, quintipara, pregnant at term, while milking, was knocked down by a cow, and struck the vulva on a corner of a box. Immediately a vulvar tumor appeared, with lancinating pain, faintness and shock; the swelling increased until she was carried to the house and placed prone. Patient was seen in half an hour; pulse was 110, respiration 30, temperature 98.

Examination.—There was found a tense globular tumor at vulva, as large as the head of a 9-pound child, elastic in consistency, purple in color, painful to the touch, and located in the right labium major. The vulvar orifice was displaced to the left, barely admitting a finger, which outlined the tumor for $3\frac{1}{2}$ inches, along the bulging right vaginal wall. No varices were apparent.

Treatment.—Under chloroform anesthesia, administered by Dr. George S. Tweedie, and with aseptic precautions, the tumor was incised, for one inch and a half, at the junction of the labial skin and vaginal membrane, where rupture appeared imminent, and over two pints of clotted blood were evacuated by the finger, with free continued hemorrhage. The cavity was irrigated and packed with sterile gauze, and a snug pudendal pad applied. The usual restorative measures were employed. The packing was partially removed next day with irrigation. On the day following, at 9:30 a. m., the remainder was removed and the cavity irrigated and dressed.

Labor.—At 2 p. m., July 6, labor commenced and a robust male child was born at 2.20. On my arrival at 2:30, examination showed that an irregular portion of right vaginal wall, about 2 inches by 1 inch, had been torn off by the descent of the head. Placenta was expelled by Credé's method. Free hemorrhage was controlled by ergot, fundal kneading, and hot irrigation.

The puerperium was normal, without a rise of temperature. The vaginal tear was irrigated and dressed daily.

This case is considered worthy of reporting for these reasons: a large, accidental, labial hematoma near term, not inducing labor, which came on naturally, yet precipitately, two days later; the partial destruction of the right vaginal wall by the descent of the head; the normal convalescence under adverse conditions.

Treatment of Angina Pectoris.—F. G. Thomson, in the *Medical Press and Circular*, states that the treatment of an actual attack of angina pectoris demands three considerations: (1) Rest, to promote restoration of heart power; (2) vasodilators, to diminish cardiac strain; and (3) morphin, to relieve the pain when this is not achieved by rest and amyl nitrite or nitroglycerin. In cases of severe spasmodic pain in middle-aged people, amyl nitrite, by lowering arterial tension, may provide instant relief; but in those cases of advanced fibroid degeneration in old people in which severe, prolonged, frequently-occurring attacks of cardiac pain render life a burden, the only drug which seems to give relief is morphin, or failing that, the administration of chloroform. In either case the relief is only temporary, and the repeated administration of one or other of these drugs may be necessary to render bearable the closing stages of a distressing and painful condition.

Therapeutics

INTESTINAL INDIGESTION

Whether there is more or less continued diarrhea or whether diarrhea is intermittent, or whether there is intestinal putrefaction, especially colon putrefaction, or simply intestinal fermentation with a large production of intestinal gas, in any of these conditions, radical changes in diet have long been found of value. As such a condition cannot long persist without causing various disturbances, such as coated tongue, bad taste in the mouth, bad breath, headache, sleepiness in the daytime and restless sleep at night, abnormal perspiration, often irritation of the kidney and even of the bladder, intestinal indigestion should be radically treated in its incipency.

It has long been shown that certain bacteria are normal in the intestine, and certain bacteria normally there cause more or less serious symptoms of toxemia if they become enormously multiplied, or under favorable conditions in the intestines for their growth, produce sufficient toxins to cause the symptoms just enumerated. Also, there may develop in the intestines bacteria which are absolutely foreign to the intestines, i. e., which are distinctly pathologic. It has also been shown that certain bacteria thrive best on protein digestive products, or rather on products of protein indigestion, and if this pabulum is removed the germs die a natural death. This same is true of certain germs that grow best in the carbohydrate by-products or digestive products, and, here again, if this pabulum is changed the germs die. The cause of putrefaction in the intestines in adults is more likely to be the results of protein decomposition. This knowledge is not frequently enough utilized in the treatment of these intestinal indigestions.

Lately C. A. Herter (*Internationale Beiträge zur Path. und Therap. der Ernährungs-Störungen*, 1910, I, No. 3, p. 275) has carefully noted the results of rapid changes in the diets of men, monkeys and cats, and finds that changes from a dominant protein diet to one in which carbohydrates preponderate were followed by definite and consistent changes in physiologic conditions in three distinct directions, viz.: a. in the nature of the intestinal bacterial flora; b, in the putrefactive products of the feces and the urine; c, in the clinical conditions.

A. Nature of Intestinal Bacterial Flora.—The chief characteristic of the dominantly protein diet is the development of a strongly prophylactic type of bacterial organisms. The mixed fecal flora in such a diet contains a high proportion of bacteria capable of proteolyzing casein actively, and of liquefying gelatin. A large proportion of the organisms may be classed in the *B. subtilis* group. In the experiments on men and cats *B. aerogenes capsulatus* also appeared. The organisms on the protein diet also possessed the power of forming an abundance of gas in dextrose bouillon. After fermentation for twenty-four hours, the gas in the fermentation tube amounted to from 60 to 90 per cent.

On changing from the protein to the carbohydrate diet, the flora undergoes a rapid change with substitution of an acidophilic, feebly proteolyzing type. Cultural investigations have shown that these organisms are allied to those characteristic of normal nurslings. The mixed fecal flora from the carbohydrate diet produces very little gas in sugar bouillon fermentation tubes

B. Putrefactive Products of the Feces and the Urine.—A well marked feature of the protein diet is the occurrence of neutral or alkaline stools containing products of putrefaction, such as indol, skatol, phenol, aromatic oxyacids, indolacetic acid and hydrogen sulphid. On the carbohydrate diet all of these substances are greatly reduced in amount, or are entirely absent. Wholly in accord with these results is the fact that the indican and the aromatic oxyacids of the urine are markedly diminished during the carbohydrate diet, and may become undetectable.

C. Clinical Conditions.—The clinical conditions were most significant in experiments on monkeys, where Herter was able to feed exclusively on hard boiled eggs for considerable periods of time. In these animals, as the proteolytic bacteria became dominant in the alimentary canal, a state of drowsiness developed. The animal remained on its perch, holding its head in its hands. It grew stupid, responded poorly to outside stimuli, and in general showed but little interest in its surroundings. As carbohydrate was added to the diet, both the psychical and physical attitude of the animal underwent a marked change. The posture became erect and the usual brightness and alertness returned. Herter believes the symptoms observed on the protein diet were signs of intoxication brought about through the excessive use of protein.

The bacterial changes in the intestine, the products of putrefaction and the clinical conditions may thus be varied at will by changing the amounts of protein and carbohydrate in the diet. It seems probable that in conditions of disease of the intestinal tract where certain undesirable bacteria abound that frequent alterations in the chemical nature of the diet may become beneficial by interfering with the establishment of any one type of bacteria in the intestine. This view harmonizes with the clinical results often obtained from variations in the diet in infancy and in adult life.

INTESTINAL INDIGESTION IN CHILDREN

Drs. John L. Morse and Fritz E. Talbot (*American Journal of the Medical Sciences*, June, 1910) have made a study of the stools of children who have had intestinal indigestion or who did not get the value of the food which they ingested. They have studied the proposition from the standpoint of actual nutrition values of the various foods and what the child needs in calories, and they find that an ordinary child four years of age needs 1,200 calories; eight years old, 1,400 calories; and twelve years old 1,600 every twenty-four hours. They believe that a child four years old needs 55 grams of protein; a child eight years old, 60 grams, and a child twelve years old, 75 grams every twenty-four hours; 5 grams may be added to the above average for boys and perhaps 5 grams deducted from the above average for girls. These are the average protein needs, and not the minimum protein need, which is roughly about two-thirds of the average amount.

These investigators find that fats may be entirely replaced by carbohydrates for a considerable period without doing harm, but there is a certain amount of risk in replacing carbohydrates entirely by fats because of the danger of causing acid intoxication or acidosis. They present a very graphic table of food values, to which the reader is referred. Suffice it to state here that a quart of ordinary milk represents 670 calories; a tablespoonful of cooked oatmeal and most other cereals, 25 calories; a tablespoonful of cooked rice, 45 calories; a potato the

size of a large egg, 100 calories; an ounce of meat, 60 calories; an ounce of beef juice, 10 calories; an ounce of butter, 225 calories; a full teaspoon of cane sugar, 25 calories; a slice of bread, 75 calories, etc.

A normal child's stool should be "homogeneous in consistency; a lumpy or mushy condition is pathologic." When lumps are present in the stools there is an excess of milk, meat or eggs in the diet, or the reverse, the child is under-fed. The child may have these lumpy stools when he is apparently getting enough in bulk to eat with a large indigestible residue but really not enough of actual nutriment. Improper chewing of food may give indigestible masses. A normal child's stool reacts to litmus paper weakly alkaline, weakly amphoteric (weakly alkaline and weakly acid), or neutral. "A very strong alkaline reaction, especially if accompanied by a putrefactive odor, suggests protein putrefaction. A strong acid reaction associated with a rancid odor suggests disturbances in the digestion of fat; if associated with the odor of lactic or acetic acid, suggests disturbance in the digestion of carbohydrates. In the latter case there is likely to be bubbles or a frothy condition."

For classification Morse and Talbot suggest dividing the stools into fatty stools, carbohydrate stools and catarrhal stools. "The fatty stools are greenish or white in color, dry or of clay-like or creamy consistency, acid in reaction, and of a rancid odor. The carbohydrate stools are brown or golden yellow in color, salve-like in consistency, acid in reaction, and acid or sour in odor. The catarrhal stools show a basis of mucus and often have a foul odor indicating protein putrefaction." The authors describe the microscopic appearance and chemical staining of the stools, but it is not the object of this abstract to discuss this detail, but to present a ready method of ascertaining, approximately at least, the character of the child's digestion. Test meals or test daily diets are not essential. It is essential, however, to know what food the child has eaten for twenty-four, or better, forty-eight hours, preceding the macroscopic and reaction study of the stool.

Morse and Talbot found in their investigations that many times the difficulties in digestion were due more to an excess in the quantity of food than in errors in quality. Brief abstracts of two of the cases that they present are of therapeutic value.

A boy $4\frac{1}{2}$ years old had five or six loose movements of the bowels a day and was losing weight. Investigation showed that he was over-fed, that the caloric value of his food was nearly twice what was needed. This was corrected, the caloric value of his food being reduced to what was the normal average, and the movements immediately dropped to two a day and the child began to increase in weight.

A boy 2 years of age had been losing color and weight for about three months, and an estimate of the food taken showed he was getting 1,200 calories per day, where approximately his needs were for only 1,000 per day. At a given date his diet for twenty-four hours consisted of 34 ounces of milk, 4 tablespoonfuls of cereal, 2 tablespoonfuls of beef juice, 3 slices of bread and a baked potato. This gave him about 1,150 calories furnished by 40 grams of fat, 130 grams of carbohydrates and 50 grams of protein. Examination of his stools, two a day, showed them to be yellow, semisolid, of foul odor, of alkaline reaction and to contain a small amount of mucus. The microscope showed that starch was not well digested, while fat was. The starch part of the food was then cut down and meat added to his diet,

and one week after the above diet it was changed to 33 ounces of milk, 2 tablespoonfuls of cereal, 2 slices of bread, a baked potato and 2 small slices of chicken. This represented about 1,050 calories furnished by about 40 grams of fat, 105 grams of carbohydrates and 50 grams of protein. His movements then became brown, soft, of uniform consistency, alkaline in reaction and contained but a small amount of mucus. The microscope showed a slight excess of neutral fat and fatty acids but no excess of meat fibers, and there was no undigested starch. The amount of milk was then cut down and the starch slightly increased, and from this time on the child has continued a steady improvement in every way.

Several instances are cited where too much fat and too much milk were given to children. Examination of the stools, with the child's diet being known, suggested proper correction. Improvement followed as proof of the needed change in diet.

The object of this article is to urge that a little more time be given by the physician in inquiring into the exact diet of a child with intestinal indigestion, or a child that is losing weight; that he personally examine one or two of the stools; that he have on hand, readily accessible, a table of the protein and caloric value of foods and a table of estimation of the average needs of a child of various ages; that he more carefully suggest or arrange the diet that is probably correct for the child, and then, week by week, modify that diet to the child's individuality. If this amount of care is taken less medicine, less tonics, less astringents, less bismuth, less lime and less change of climate will be needed to rescue the young child from more serious conditions than that we are discussing.

CHRONIC COLITIS

Any treatment that has proved of value in chronic inflammation of the large intestines should be noted. Ludwig von Aldor (*Therapeutische Monatshefte*, 1910, xxiv, No. 4, p. 171), after several years of investigation, has come to the conclusion that flesh food should be largely or entirely removed from the diet during chronic colitis. He also has found benefit from the local application of hot gelatin solutions. For this purpose the patient receives a rinsing enema of a pint of water at a temperature of 77 to 83 F. (25 to 28 C.) one hour before the gelatin injection. He is then made to rest in bed for at least half an hour. From 40 to 80 c.c. ($1\frac{1}{3}$ - $2\frac{2}{3}$ fluid ounces) of a 10 per cent. gelatin at a temperature of 113 to 125 F. (45 to 52 C.) are then injected, with the patient lying in bed on his left side. The abdomen is covered with a hot compress and the patient is kept perfectly quiet for two hours. In many cases the gelatin is completely retained by this procedure. Von Aldor puts much emphasis on the high temperature of the gelatin solution. A temperature of 113 to 122 F. (45 to 50 C.) is very easily borne by the large intestine.

Usually the patient passes a well-formed stool several hours after the injection. The injections are given every day until complete recovery occurs, which is in from three to fourteen days. This treatment is absolutely harmless and has proved effective in all cases in which the author has tried it. He believes that the therapeutic value is due:

1. To the high temperature.
2. To the use of non-fermenting substance for injection.
3. To the absorption and mechanical removal of the bacteria and intestinal excretions by the gelatin.

WATER FILTRATION AND TYPHOID FEVER

The significance of the continued high rate of typhoid fever in Washington, D. C., after the installation of a supposedly model filtration plant, is again brought up for discussion, this time by H. W. Hill.¹ The facts of the situation are sufficiently remarkable to bear repetition. Here was a well-sewered city with a relatively high typhoid rate; the apparently excessive prevalence of the disease extended over many years and was attributed by those who studied the situation to a contaminated drinking-water. No dissenting voice was raised against this conclusion. In the instructive controversy over the relative merits of slow sand filters and mechanical filters which preceded the construction of the Washington filter-bed no one seems to have questioned that the supply of water from the Potomac river was highly polluted. The numerous committee reports and discussions of ten years ago abound in statements like the following: "Filtration of the Potomac water on a large scale is imperatively called for in order to diminish the excessive typhoid fever death-rate in the national capital." As the outcome of years of persistent agitation the construction of a filter-bed on the principle of slow sand filtration was finally authorized, and since October, 1905, the City of Washington has had an uninterrupted supply of filtered water.

Now, the surprising sequel is that the presumptive improvement in the character of the Washington water-supply due to the construction of the filter did not lead at once to a noteworthy reduction of the typhoid death-rate. Contrary to the experience of Lawrence, Albany and other American cities which have installed slow sand filters, the typhoid rate in Washington showed no immediate decline, but was even somewhat higher the year following the use of the filter than in the three years immediately preceding! This unexpected outcome sowed seeds of dissension in the councils of sanitarians. Some were at once for throwing over slow sand filtration as a method of water purification; others maintained that water could never have been an important factor in the causation of typhoid fever in Wash-

ington, and still others attributed the continued prevalence of the disease to defective operation of the filters.

It is fortunate indeed that the study of the situation thus outlined has fallen into competent hands. Under the auspices of the Public Health and Marine-Hospital Service three reports on typhoid fever for the years 1906, 1907 and 1908 have been issued, and a fourth report for 1909 is in preparation. These reports are models of careful observation and accurate gathering of statistics, but they have not given satisfaction to some sanitarians because they did not arrive at "definite conclusions." Others, while not objecting to the indefiniteness of these reports, have criticized their hints at mysterious causes and unknown factors. Others again, among whom Hill is one, frankly disagree with the conclusion of these reports that the filtered water-supply of Washington has played a relatively minor part, if any, in the causation of typhoid fever.

This well-known sanitarian, in the article just cited, avows his belief that "the vast majority of the native primary cases of typhoid fever in Washington otherwise unaccounted for are due to infection conveyed to them by the Washington water." It may be so. Every one knows how difficult it is to prove the negative of such a proposition. At the same time, if analogy and experience count for anything, the evidence, in order to be conclusive, not only must demonstrate the continued possibility of infection from the improved water-supply, but must practically exclude the possibility of infection through other channels. On the one hand, as we have mentioned before,² there is a possibility that carriers, infected by a previous polluted water-supply, may hand on the infection after the water has been purified and made safe. On the other, no one has yet brought forward any evidence to show that the Washington filters are more poorly constructed or more carelessly operated than the similar filters in Lawrence, Albany, Hamburg or London. It will be hard to convince sanitary authorities generally that a filtered water, in which only one out of seventy 10 c.c. samples contained the colon bacillus, is not a fairly safe water as filtered waters go. Evidence rather than assertion is needed. Hill suggests that a few months' sterilization of the water with hypochlorites would eliminate all doubt concerning water infection. Some such procedure as this would seem well worth while, since competent judges of the situation are so completely at variance.

Whatever be the explanation of the Washington situation, there is no need for discouragement on the part of the advocates of filtration. The reports coming in every day from various other cities that have adopted this method of water purification are uniformly favorable. Typhoid mortality in Philadelphia has fallen from 74.8 in 1906 to 21.2 in 1909, the mortality in the latter year being the lowest in the history of the city. Within three

months Philadelphia has seen two entire weeks pass without a single death from typhoid fever. Columbus, Ohio, reports only 209 cases of typhoid and 20 deaths the first year of the filtration plant (1909), as against 1,565 cases and 170 deaths in the year preceding. The use of a settling basin in Richmond, Va., has been followed by a reduction in typhoid mortality, there being only fifteen cases reported in July of this year, as contrasted with eighty-eight in July, 1909. There is still ground for believing that storage and filtration are effective agencies of water purification.

PHARMACOLOGY AND THE CLINIC

Now that clinicians are using drugs more and more on the basis of experimental observation, both clinical and laboratory, it is of interest to read what Professor O. Loewi has to say on the subject in his inaugural address as professor of experimental pharmacology at Graz.¹ Loewi is a pharmacologist of the Schmiedeberg school, which has to its credit on the one hand the clearing up of the tremendous amount of rubbish which had accumulated in the Pharmacopeia, and on the other hand a wise moderation in refusing to follow blindly the bold flights of modern immunology. As he points out, it is in the study of fundamental cell problems, such as the physical properties of the colloids and the chemistry of the cell, by the methods peculiar to itself, that the future of pharmacology as a fundamental science must depend. The subject cannot be of real practical use until it has first established itself on such a basis.

To mention a few brief examples which Loewi uses to illustrate how cooperation between pharmacologist and clinician can lead to practical results: The fact that clinicians sometimes fail to obtain at the bedside results which laboratory observations might lead them to expect has been attributed to the difference in the behavior of drugs in the normal and diseased organism. Both pathology and pharmacology teach that in many instances this difference in reaction of a given organism, when not associated with actual destructive changes, is a mere matter of variation in irritability. The problem of treatment then becomes a matter of dosage. In case of intestinal colic, in which the clinician was inclined to condemn the use of the usual one-milligram (1/60 gr.) dose of atropin on account of the development of toxic symptoms, the dose was reduced to the unusually small amount of one-twentieth of a milligram (1/1200 gr.). Not only were the toxic symptoms eliminated but the desired therapeutic result was obtained. Just as in lead-poisoning the presence of the lead renders the intestine so much more irritable that a dose of atropin, which would have very little demonstrable effect on the normal intestine, can relieve the symptoms, so here, by a pathologic condition the intestine had been rendered so irritable as to react to a minute dose.

The opposite condition, or decreased irritability, also sometimes has to be met. To treat this condition by an increase in dosage is not always wise, unless the clinician has a very definite knowledge of the complications to be expected, a point about which the pharmacologist should be able to give him information. Another means of meeting the difficulty of lack of irritability has lately been receiving more nearly the attention that its importance deserves, namely, the combination of two drugs. To illustrate: The loss of tone of the musculature of the intestine after surgical operations often fails to be relieved by pilocarpin. By the use of physostigmin, which increases the irritability, in combination with pilocarpin, which then stimulates, the desired result can often be obtained.

The treatment of a condition by the careful physiologic analysis of the functional disturbances involved, combined with the application of the drug based on a knowledge of its action, is shown in the following: A case of angina pectoris vasomotoria: heart symptoms, pressure in the chest, a feeling of intense fear appearing on exposure to cold. The physiologic analysis makes the following chain of events likely: Cold causes peripheral vasoconstriction; this leads to increased blood-pressure which exerts a stimulus on the depressor nerve, which in turn stimulates the vagus center and thus leads to the heart symptoms. The whole or part of this chain is probably in a condition of increased irritability, as normally such a result would not be observed. Instead of decreasing the irritability of the factor involved, however, it is necessary only to interrupt the chain by the administration of atropin, which paralyzes the vagus endings in the heart. The patient can now dip his hands into ice-water without any feeling of distress, which, however, comes on again when the effect of the atropin wears off.

The close affiliation of the clinician and the pharmacologist here outlined, besides being of practical use to the former, must of necessity be a great stimulus to the latter, provided he does not permit the urgency of the immediate solution of clinical problems on the basis of insufficient knowledge to influence unduly the direction of his investigations.

FERRO-SILICON POISONING

Improved manufacturing methods involving chemical processes, while they are intended to cheapen output or improve quality, often have effects inimical to health or may even menace life. This fact is illustrated in the case of ferro-silicon. The sudden deaths that have occurred among the crews of vessels laden with this product and illness among workmen in steel works from its fumes have led to an official investigation¹ of the cause. McWilliam² recently has given an account of accidents of this character occurring on vessels, and

haps they never were as numerous as we think. In any case, it is well for us occasionally to take time to hold up for honor and emulate the fearless honesty and the devoted unselfishness which distinguished the most worthy representatives of the old school.

Current Comment

COMMON SENSE TREATMENT OF DISTURBANCES OF THE BOWELS

In the Therapeutic Department of this issue is brought out an important matter: the necessity of regulation of the diet to correct disturbances of the bowels. It would be absurd to suggest that physicians are not mindful of this necessity, but it is certainly true that quite often not so much study of individual cases is made as the condition deserves. It is well to remember that a little change in diet may be far more effective than the small doses which it is possible to give of antiseptics, digestants, or correctives. This point was emphasized last week in the Pharmacology Department, in the comment on the futility of giving minute amounts of digestants. It should ever be kept in mind that food may be either a most potent agency for repair or a tremendous handicap.

WHITE PHOSPHORUS IN MATCHES

The United States is practically the only important civilized country which has taken no steps to prevent the use of white phosphorus in the manufacture of matches. That phosphorus poisoning occurs in this industry in the most serious form has long been known; but the fact is again confirmed by a recent investigation of American match factories by the Bureau of Commerce and Labor. THE JOURNAL news correspondence from European cities has frequently called attention to the fact that Europe has long been taking steps to safeguard workmen; there the use of white phosphorus is being restricted so that eventually it will not be used. This country would have been the first to take action on this matter had it involved a commercial proposition; but, since it is a matter that merely affects the health of the workers, it is different.

HEALTH OF WHITE MEN IN THE CANAL ZONE

The construction of the Panama canal is a problem in sanitation first and an engineering problem only secondarily. This THE JOURNAL has repeatedly asserted, as also that the sanitary difficulties have been met in a remarkably successful manner. The engineering work seems to be progressing toward an equally happy conclusion. The success of the canal itself seems, therefore, assured. But there is another fact connected with the building of the canal which is worth calling attention to. Colonel Gorgas in his address before the American Society of Tropical Medicine¹ expressed it as his conviction that the greatest good the canal had

done is that it has given another demonstration of the fact that the white man can live and do the same work in the tropics as he can in the temperate zone. It is shown that health conditions in the Canal Zone among the unacclimated men, women and children from the United States are as good as in any healthy part of the United States; also that the sanitary surroundings of the native and the negro have been so changed that they enjoy the same degree of health as the ordinary inhabitant of the United States. Colonel Gorgas also believes that the criticism that the expense of sanitation in the Isthmus has been excessive is unwarranted. He points out that the work of the Sanitary Department of the Isthmus has been much broader than the ordinary work of a health department, and that it performs the same functions as the whole city government of New York City with the exception of the accounting system, the judiciary and the police. As a matter of fact the medical and hospital care of the employees and their families has cost two and one-half cents per diem per capita, and their sanitation nine mills per day, which he believes to be well within the financial ability of any tropical community. Aside from the great object-lesson presented by the sanitation of the Canal Zone, Colonel Gorgas calls attention to the fact that history shows that great local populations and great wealth have grown up where routes of commerce converge between great divisions of the world. In the case of Panama more routes of travel converge, a greater area of territory is affected, and the concentration of routes is brought into narrower limits than has ever occurred before. He expects in the course of years to see a large and wealthy population grow up in the neighborhood of the canal.

VEGETABLE ACTINOMYCOSIS

Under the title *Die pflanzlichen Actinomycosen*, Peklo¹ has published the results of a comprehensive study of the organisms found in the root tubercles of the alder and sweet gale (*Myrica gale*). As indicated by the heading given to his communication, he has arrived at the conclusion that these micro-organisms are to be considered as belonging to the group actinomycetes. "Clubs" and other characteristic actinomycotic growths were found to be produced by the "bacteroids" under appropriate cultural conditions; and certain chemical substances such as phosphates and potassium and calcium salts appear to favor especially the growth of the root tubercle organisms. Peklo has utilized his observations on the physiology and morphology of these forms as a basis for a fresh study of the human tubercle bacillus. By the use of analogous culture media he succeeded in producing in cultures of the tubercle bacillus structures showing a remarkable morphologic similarity to the growths from the alder nodules. In fact he concludes definitely that the tubercle bacillus is an actinomycete. Interesting and perhaps fundamental analogies in the chemical relations and pathologic activities of these organisms are pointed out. Such observations are well worth attention, although they are perhaps more suggestive than conclusive.

PRESS CENSORSHIP IN AMERICA

Under this heading, the *Christian Advocate* of New York comments on the way in which the brewing interests keep watch of the attitude taken by newspapers and other periodicals. This relationship is so similar to that existing between the patent and proprietary medicine business and lay and medical periodicals, that its comments are easily made to apply to the latter by changing a few of the words. After remarking that a part of the financial embarrassment of the *Boston Herald* is due to the withdrawal of brewers' advertising, because that paper vigorously supported a bill which was antagonistic to the saloon interests and, further, that the *Chicago Tribune* recently lost a large amount of beer advertisements because an editorial on hot weather hygiene recommended abstinence from beer, the *Christian Advocate* continues: "It is loudly denied that there is any concerted action among the brewers ['patent medicine' manufacturers] to control the utterances of the press by dispensing advertising patronage, but it is easy to see how self-interest might prompt such action as that by which the *Herald* and the *Tribune* have been the sufferers. We regret that a newspaper should lose money by standing for a principle, but we cannot but believe that the public is the gainer by the transaction, and that if all the liquor and beer and tobacco advertising [fraudulent patent medicine and quack advertising] were withdrawn, both the newspaper publishers and their subscribers would be the better off, for if money were not wasted on beverages and tobacco [nostrums] it would be available for the purchase of other commodities which in turn would be an advantage to manufacturers, dealers and advertising mediums...Any one who takes the trouble to compare the editorial and news policy of many periodicals with the advertising columns will find grounds for belief that the liquor [proprietary medicine] advertisements strongly influence, if they do not control, the editorial policy."

Medical News

CONNECTICUT

Personal.—Dr. William F. Verdi, surgeon in charge of the St. Raphael Hospital, New Haven, has resigned. Dr. Verdi had the title of chevalier conferred on him by the king of Italy.

Tuberculosis Homes.—The State Home for Tuberculosis Patients at Meriden and the home in Fairfield County at Shelton were opened August 1. The home at Cedar Mountain is also practically ready for opening.

Epileptic Colony.—The commission, appointed by Governor Weeks, under the act of the last general assembly, has purchased the Rock Spring Farm at Mansfield as a site for a state epileptic colony. Dr. Max Mailhouse, New Haven, was a member of the commission.

Show No Mortality.—According to the monthly bulletin of the Connecticut State Board of Health for July, twenty-five towns of the state report having no deaths during the month. The death rate for the state shows 19.3 per 1,000. Infantile paralysis was reported from five towns, there being 18 cases during the month.

Appropriation Asked.—The board of health of New Haven has asked the board of finance for an appropriation of \$400,000 for health purposes for 1911, \$100,000 of which is for collection and reduction of garbage, \$220,000 for a garbage incin-

erator, and \$75,000 for a contagious disease hospital. Last year only \$33,000 was appropriated for the work of the department.

GEORGIA

Uniformed Inspectors.—Inspectors of the board of health of Augusta are to be fully uniformed in a manner similar to the police.

Personal.—Dr. Howard J. Williams has resigned from the medical board of Macon Hospital, to take effect October 1. —Dr. Bernard Wolff has resigned from the board of health of Atlanta, and has been succeeded by Dr. Rufus T. Dorsey. —Dr. T. Neal Kitchen, formerly of Columbus, has resigned as president of the Muskogee County Medical Society and has moved to Warm Springs. Dr. Dexter becomes president of the county society.

To Complete Sanatorium.—The state legislature has made an appropriation of \$50,000, \$30,000 for completing the buildings and equipping the new state sanatorium for tuberculosis, and \$20,000 for maintenance during 1911, as provided for in the bill introduced by Dr. Hardman of Jackson County, and Dr. Brown of Fulton County. —Fulton County Commissioners have appropriated \$10,000 of the county funds to aid in the erection of a tuberculosis sanatorium at Atlanta.

Uncinariasis Common.—According to the newspapers, Drs. S. H. Jacobs and C. H. Dobbs, field inspectors for the Georgia State Board of Health, who have been making a tour of inspection of the state since early in May, found that over 75 per cent. of the people of Georgia who live in the country districts have or have had uncinariasis. To August 1, out of 1,055 persons examined, 672 showed the disease. In Emanuel County, 42 out of 43 inspected had the disease. Many school children have been examined and in every instance ground-itch has been found.

ILLINOIS

Anthrax Among Cattle.—It is said that anthrax has made its appearance among cattle on a farm at Barrington and 16 have died from the disease. It is so far confined to one farm.

Medical Inspection at Macomb.—Drs. Arthur R. Adams, John W. Hermetet, S. Frank Russell and Arthur K. Drake have been appointed by the Board of Education of Macomb to institute medical inspection of the school children. On account of the financial condition of the city, the work will be done by these physicians gratuitously.

Personal.—Dr. Harry W. Ackermann, Rockford, has been appointed first lieutenant of the Third Regiment of the National Guard. —Drs. Malford Hamm, Lay G. Burroughs, and Edgar A. Cook have been appointed township physicians at Edwardsville. —Dr. Julius H. Hess, Chicago, has returned from four months spent among the pediatric clinics of Europe.

Homes for Convalescent Insane.—The Society of Mental Hygiene, recently organized in Chicago, as part of its method of looking after patients who have been in insane hospitals, will endeavor to place patients either recovered or on the way to recovery in homes on farms and elsewhere. This plan has been tried in other states and to some extent in Illinois. The crowded condition of the hospitals for the insane has made this almost a step of necessity. Dr. Vaclav H. Podstata, formerly superintendent of the Elgin State Hospital, has been given charge of this work, and Miss Elnora Thompson, until recently head nurse at the state hospital but now of Hull House, is assisting. The after-care committee will endeavor to extend the work and put it on a more responsible basis.

Chicago

Birth Returns.—The Chicago Woman's Club has called attention to laxity in enforcing the ordinance requiring the reporting of births within thirty days by physicians and midwives, and suggests that the health department should enforce the law in this respect. One of the daily papers commenting on this action says that only vigorous enforcement of the ordinance and application of penalties for neglect to comply, without discrimination, will bring about a needed improvement in Chicago's vital statistics.

An Appreciation of Dr. Ricketts.—The *University of Chicago Magazine* for July contains an obituary of Dr. Howard T. Ricketts and an article in appreciation by Dr. Ludvig Hektoen. Dr. Hektoen says that important results in the battle against infectious diseases will follow the work of Dr. Ricketts, who died of typhus fever in Mexico in May, and he believes that the publication of the typhus researches of

Dr. Ricketts and Mr. Wilder in their final form will settle the moot questions regarding the disease.

Health in Chicago.—The mortality statement for the week shows an improvement over the corresponding period of last year, especially in respect to infant mortality. There were 42 fewer deaths under one year of age and 22 fewer under five years of age. Deaths from diarrheal diseases among children were 53 fewer than during the corresponding week of last year. Ice cream is still being given attention by the health department and the study of typhoid fever under Dr. Lumsden still goes on. During the week ended August 19, 78 cases of typhoid fever were reported as against 40 for the corresponding week of 1909.

Examination of Carbonated Waters.—The *Bulletin of the Chicago Health Department* for the past week gives the results of the examination of 66 samples of carbonated water in the form of seltzer, ginger ale, pop, or sodas of various colors. It was found that 18 of them contained lead; in 3 samples $\frac{1}{4}$ grain per gallon; in 3 samples, $\frac{1}{10}$ grain per gallon; in 8 samples, $\frac{1}{20}$ grain per gallon; and in 4 samples, $\frac{1}{40}$ grain per gallon. Eight factories were found marketing the waters containing lead; six were closed, and the other two ordered to improve their equipment or methods. The pops sold in bottles stoppered with metal stoppers were the objectionable ones. It was found that the stoppers contained from 50 to 90 per cent. of lead. Investigation was undertaken at the suggestion of one of the physicians of the city who, in an investigation, found that numerous cases of illness among children were caused by these carbonated waters.

INDIANA

Hospital at Frankfort.—The new tuberculosis hospital at Frankfort was opened August 9. The hospital consists of an administration building and six cottages for patients, located on a tract of five acres of beautifully wooded land.

Library Destroyed.—The office of Dr. James A. Stafford, Millville, was destroyed by fire recently, burning up his library and complete record of cases of fifty years of practice, which Dr. Stafford had ready for publication in book form.

Deaths and Births in Goshen.—Dr. Albert C. Yoder, secretary of the city board of health, Goshen, reports 8 deaths and 21 births for the month of July. This means an annual death rate of 10.66 to the 1,000 and an annual birth rate of 28 to the 1,000.

Tuberculosis Farm.—Tent houses have been erected on the tuberculosis farm at Evansville, known as the Boehne Farm, in honor of Congressman John W. Boehne, who gave \$10,000 to the farm during the last year. A brick hospital building is being erected.

Advocates State Pasteur Institute.—Dr. William G. Wegner, county health commissioner at South Bend, advocates the establishment of a state Pasteur institute for the prevention of rabies. He favors the addition of 25 cents to the dog tax to create a fund for this institute.

IOWA

Homeopathic Graduates.—Dr. George Royal, dean of the homeopathic department of the State University of Iowa, calls attention to an error in the total number of graduates given for that school in *THE JOURNAL*, Aug. 20, 1910, the Educational Number. The number of graduates reported was eleven instead of seven. This correction increases the number of homeopathic graduates for the entire country to 183 instead of 179.

KENTUCKY

Personal.—Dr. Henry McKenna has been appointed intern in St. Joseph's Hospital, Louisville. —Dr. William V. Neel, health officer at Henderson, has undergone an operation for appendicitis. —Dr. James C. Mitchell, Louisville, has been appointed a member of the State Board of Health.

Tuberculosis Dispensary.—The dispensary organized by the Louisville Antituberculosis Association as the first dispensary of its kind in the city has shown great growth since its organization. There are now 287 persons under its care. During the past month 1,051 visits have been made to patients by Dr. A. M. Forster, who is in charge of the dispensary, and by the staff of four visiting nurses who give all their time to the work.

Enforcing Health Ordinances.—It is reported that Health Officer Edward Grant of Louisville is endeavoring vigorously to enforce the ordinance in regard to reporting notifiable dis-

cases. He recently swore out warrants for five physicians for failure to report cases of typhoid fever under their care. It is said that many cases of typhoid and other contagious diseases have not been reported as required. Dr. Grant has also had the school buildings of the city inspected during the vacation season and many sanitary improvements have been recommended.

State Health Board Appointments.—At the annual meeting of the State Board of Health at Louisville, August 11, the following heads of new offices in the health department, created by the last general assembly, were appointed: Dr. W. Lucien Heizer, New Haven, superintendent of vital statistics; Dr. Lillian H. South, Bowling Green, state bacteriologist; Prof. Frederick Mutchler of Western State Normal School, assistant state chemist; Dr. Paul Hansen, formerly of the Ohio State Board of Health, was elected state sanitary engineer. Dr. Joseph N. McCormack, Bowling Green, secretary of the board, made his annual report in which he stated that there were 129,717 cases of illness in the state during the past year, 6,500 of which were due to tuberculosis. He estimated that the cases of sickness cost an average of \$94 for medical care, drugs and loss of time, placing a total annual tax on the people of the state of over \$12,000,000, nearly double the total annual revenue of the state. The report goes on to say that in order to prevent at least a large portion of this loss, "so far as this generation goes, an appeal to the common sense of the business world gives greatest promise of success. The facts and the losses need to be verified and iterated and reiterated for their significance to be recognized. The employing classes want to live, and in a way want their employees to live. If shown that it would be cheaper to improve sanitary conditions and keep their employees well than to bring in immigrants to die of the same neglect, and that they and their families are likely to sicken and die prematurely from the same causes, it would impress them."

LOUISIANA

Screens in Public Markets.—Dr. William H. Block, acting secretary of the New Orleans Medical Society, has presented to the mayor of New Orleans copies of resolutions adopted by the society, advocating the screening of public and private markets in the city where food is exposed for sale. Dr. William T. O'Reilly of the city board of health, has also reported that he would introduce an ordinance in the council for the same purpose.

The Uncinariasis Commission.—The State Board of Health has authorized the appointment of a medical inspector to be placed at the head of the new department of the State Board of Health for the eradication of the hook-worm. The inspector will receive a salary of \$3,000 a year, of which sum the Rockefeller Hook-Worm Commission, through Mr. Wickliffe Rose, has guaranteed \$2,500 and the traveling expenses of the inspector, as well as the salaries of other assistants.

Antituberculosis Camp.—The Louisiana Antituberculosis League has established a camp at Todd for the treatment of incipient cases of tuberculosis. The second and third stage patients will be cared for by the Charity Hospital with the aid of the legislature, which during the last session appropriated \$10,000 a year for their care at that institution. The camp consists of a hotel which cost \$6,000, and eight cottages each costing \$400. An artesian well has been bored and the water is reported to be of good quality. The camp is said to have an ideal site for the purpose.

Personal.—Dr. D. Harvey Dillon, president of the State Board of Health, and Dr. Edward S. Kelly, secretary, have resigned. —Dr. Edward L. McGehee has been made president of the reorganized State Board of Medical Examiners; Dr. John G. Martin, vice-president, and Dr. Albert B. Brown, secretary-treasurer. —Dr. John B. Elliott, Jr., New Orleans, has been promoted to the chair of theory and practice of medicine to fill the place made vacant by Dr. George Dock. —Dr. C. W. Groetsch, New Orleans, is spending the summer in Canada, where he is making a study of Canadian hospitals.

MARYLAND

Quarantine Established.—Quarantine has been declared at Fort Washington on the Potomac below Washington, on account of the breaking out of scarlet fever in Company 44 of the Coast Artillery there.

Meat Condemned.—Dr. J. McPherson Scott, mayor of Hagerstown, has started a crusade against the selling of unwholesome meat there. One-half of ten carcasses exposed

for sale were condemned as unfit for food by the state live stock inspector.

For a Hospital.—The Board of Trade of Havre-de-Grace has taken up the project of a hospital in that town, and has appointed a committee to investigate hospitals in similar towns. A temporary hospital of 25 beds will meanwhile be provided and subscriptions will be raised and the legislature will be asked for an appropriation; \$3,000 annually is required.

Endowment for University.—A strong appeal is being made for contributions to the endowment fund of the University of Maryland. The institution is now in its one hundred and third year and it is claimed that it is a civic duty of the people of Maryland to give it financial aid. It has not shared in the benefactions of this community as it should and as other similar institutions here have, and such an appeal should meet with generous response from our public-spirited citizens. A considerable sum is already in hand and invested in safe securities. The charter makes the principal inviolable. A large part of this fund belongs to the medical department, including endowments of three scholarships and one chair (physiology). A vigorous campaign will be made on this behalf this fall.

Baltimore

Personal.—Dr. J. M. T. Finney has returned from Europe and is at Chester, Nova Scotia.—Dr. Thomas Shearer is at Ontario, Canada.—Dr. Howard A. Kelly is visiting London and Paris clinics.—Dr. Donna Waldran is in Edinburgh.

Typhoid Fever.—For the week ending August 20, there were 121 cases of typhoid fever reported, with 11 deaths. Eight cases have been reported in Troop A, which camped at Gettysburg in July, and the governor has called on the State Board of Health to make an investigation.

New State Laboratory.—The new laboratory at the State Health Department for the examination of water, milk and ice cream under the pure food law, was ready for work August 22, and the inspectors have entered on their work under Dr. Charles Caspari, Jr., state pure food commissioner.

Medical College News.—The Maryland Medical College announces that the day courses for first and second year students will be continued as usual, in addition to the evening courses recently announced for the same.—The College of Physicians and Surgeons announces that for the next session not more than 75 students will be admitted to either the freshmen or sophomore classes. The addition to Mercy Hospital connected with this college has reached the second floor. It will more than double the size of the hospital.

Discoverer of Saccharin Dies.—The death of Dr. Charles Fahlberg is announced at Bad Nassau, Germany, August 16. It was he who, working here with Remsen and under Remsen's direction and in Remsen's laboratory in 1879, made the discovery of saccharin. Shortly after, he left here and went to Germany, where he patented the product and amassed a fortune out of it. For this discovery Remsen was awarded a medal at the St. Louis Exposition in 1904 by the Society of Chemical Industry of England. Saccharin is a coal-tar product, and when pure possesses about 500 times the sweetening power of cane sugar. It is extensively used in the manufacture of canned goods when pure food laws do not prohibit it.

NEW YORK

Personal.—Drs. Roswell Park and Charles Cary, Buffalo, and A. J. Bedell, Albany, have returned from Europe.—Dr. Harry Weed, Buffalo, and Dr. E. C. Taylor, Dr. and Mrs. W. M. Butler and Dr. Alfred C. DuPont, New York City, have sailed for Europe.

Scarlet Fever and Diphtheria.—The mortality from scarlet fever is becoming alarmingly large. In July, 1909, there were 140 cases of scarlet fever reported, with 9 deaths, or 6.4 per cent., while in 1910 there were 156 cases of scarlet fever reported, with 15 deaths, or a mortality of 9.6 per cent., an increase in mortality of nearly 3.2 per cent. over the same period of last year. It can safely be predicted that with this showing for the summer months with the opening of schools in the fall scarlet fever will continue epidemic, and that the mortality will increase. In July, 1909, there were 24 cases of diphtheria reported, with 1 death, a mortality of 4.1 per cent.; in July, 1910, there were 60 cases of diphtheria reported, with 13 deaths, a mortality of 21.6 per cent.

Buffalo

Tuberculosis Hospital.—Bids were opened August 13 for the building of the county tuberculosis hospital at Brighton,

near Rochester, the lowest being a little more than \$60,000. The work includes an administration building, nurses' home, a number of cottages and a sewage disposal plant.

Preventing Pertussis.—To stamp out the present epidemic of pertussis before the schools open, the Health Department has adopted a method similar to that used in Seattle and Chicago for other diseases, namely, to display between regular pictures at the moving-picture theaters slides prepared by the health department relating to the dangers of pertussis and the means which should be adopted to prevent its spread. Acting Health Commissioner Scahaefer has already placed the moving-picture houses and pleasure steamers under surveillance, so that persons suffering from the disease may be apprehended. Pertussis caused 782 deaths in the State of New York last year.

New York City

A Roof Garden for Babies.—What is believed to be the first regular roof garden for ailing babies has just been opened at the Flower Hospital. This garden has been constructed along the accepted styles for roof gardens even to the music and entertainments. In clear weather the roof garden does duty for the entire twenty-four hours, being used as a dormitory at night. Large returns in the way of improved health among the babies is expected from this innovation.

The Sale of Morphin.—A drug clerk was recently arrested for selling morphin; the purchaser was also arrested. The assistant district attorney refused to have the complaint pressed. The clerk had registered the sale and the note "she has the habit." It seemed, therefore, that there had been no violation of the law. The sale of morphin is legal, it seems, providing it is properly labeled. The Board of Health has power to amend the sanitary code and place the sale of morphin on the same basis as that of cocain.

A Large Foundation.—Mr. John Masterson Burke of New York announced some eight years ago that he would make a foundation in order to endow a home in or near New York for convalescents. At the time of Mr. Burke's death last December, this foundation amounted to \$5,000,000, and personal property has been added to the amount of \$2,000,000. The will was contested by relatives, but the court has decided that it is valid. There is, therefore, about \$7,000,000 with which to begin building, but fear of further litigation will make it advisable to postpone active work for some time.

OHIO

For Cleaner Food.—The City Board of Health of Washington has passed resolutions making stringent regulations for dealers in all classes of food supplies in regard to keeping food clean, and also for the disposal of garbage and taking care of slaughter houses.

Visiting Nurse Provided.—The physicians of Springfield having in charge the free milk dispensary have hired a nurse to visit the families where babies are being treated at the dispensary to see that the suggestions of the physicians are carried out regarding the care of the children and to locate other children requiring dispensary care.

Personal.—Dr. Jane W. Carroll has been elected supreme medical examiner of the Ladies' Catholic Benevolent Association at Cleveland.—Dr. Otis L. Cameron, Cincinnati, has resigned as a member of the board of health. Dr. John D. Miller has been appointed to fill the unexpired term.—Dr. A. Garner, Hillsboro, president of the city council, has become mayor through the resignation of Mayor Puckett.—Dr. Oscar H. Sellings, a member of the Columbus City Board of Health, has been elected to the chair of children's diseases in the Starling-Ohio Medical College.

Tuberculosis.—Toledo has established its first outdoor camp for patients with tuberculosis on a tract of ground comprising several acres, the use of which was given by Judge John F. Kumler. There are about twenty patients in the camp, housed in tents. The work will be extended throughout the winter.—City Health Officer Clemmer of Columbus has asked the local board of education to provide for the building of open-air rooms for tuberculous pupils in all new school buildings to be erected by the board.—The first city tuberculosis dispensary in Cleveland will be located in the Eighth Precinct police station, where four rooms will be fitted up for the purpose. Two of the six city nurses will make the rooms their headquarters and a ward physician will have daily office hours there.

School Inspection.—Dr. Louis F. Bucher, Dayton, who has been appointed by the board of education to begin medical

inspection of school children, has just returned from a six weeks' eastern tour, where he has studied the system employed in various cities, and will inaugurate a systematic plan of keeping records of the inspection of the school children in Dayton.—Medical inspection of the school children will be inaugurated this year at Youngstown, and four nurses have been employed, whose duty it will be to visit the schools daily and inspect sanitary conditions and look after suspicious cases of skin troubles, infectious diseases, etc., among the children. At the beginning of the term, the work will be started by four physicians, who will make a thorough examination of all pupils.

PENNSYLVANIA

Smallpox in State.—Fifteen cases of smallpox have been reported from Honesdale, Herick Center and Tanners Falls. Men from the state health department have been detailed to look after these cases.

Typhoid at Wilkes-Barre.—The typhoid epidemic at Wilkes-Barre has become so serious that action has been taken against the company supplying water to the city for non-compliance with the ordinance requiring filtered water. The water company, it is understood, does not regard the ordinance as valid.

Cresson Sanatorium.—Bids for four of the buildings for the tuberculosis sanatorium to be erected at Cresson Springs on the ground given by Andrew Carnegie were opened at the state health department August 9. The buildings will be of stone procured on the ground. The sanatorium will cost \$250,000, exclusive of equipment.

Bad Conditions Exist at Dixmont.—Dr. Frank Woodbury and Francis J. Torrance, secretary and president, respectively, of the State Board of Charities, denounce the conditions existing at the Dixmont Asylum for the Insane. They found 997 patients in the institution, while the building was erected to accommodate 500. Steps are to be taken to distribute patients to other institutions.

Report of Pure Food Crusade.—During Governor Stuart's administration, from January, 1907, to Aug. 1, 1910, according to the report of the State Dairy and Food Commissioner, 2,093 prosecutions for food adulteration have been brought, of which 861 were under the oleomargin act. The fines collected from these cases totaled \$105,964.84, and 11 men were committed to jail for terms of from 20 days to 6 months each.

Philadelphia

Arrests Reveal Renewed Cocain Traffic.—The cocain traffic, practically wiped out by the recent crusade of the State Pharmaceutical Board, has again been resumed. Two men charged with the illegal sale of the drug in large quantities were arrested, August 19, by an agent of the board and held in \$1,500 bail each for court.

Children's Pavilion for Jewish Sanatorium.—The Philadelphia Jewish Sanatorium for Consumptives has completed plans for a children's pavilion at the farm at Eagleville. In this pavilion children less than 12 years old will be treated free. Of the \$5,000 necessary for the erection of this pavilion, \$1,250 has been donated by a friend of the institution.

Tuberculosis Traced to Cheap Ice Cream.—A dozen cases of dangerous infection have been traced to the confection which is sold by the push cart vendors. Follicular tuberculosis has been traced to this ice cream. An investigation has been started by the State Dairy and Food Commission, and prosecutions will follow as soon as the samples have been analyzed.

Egg Dealer Held for Court.—At a hearing, August 16, of a man charged with selling eggs unfit for food, testimony was given that the defendant had sold eggs which, when fed to guinea-pigs, had killed them. These eggs were examined by Professor LaWall, chemist for the State Dairy and Food Commission, and Dr. Randall C. Rosenberger, of the Jefferson Medical College, and were found to contain 10,000,000 bacteria to the c.c.

Personal.—Dr. James Hendrie Lloyd has been elected visiting neurologist to the Methodist Hospital.—Dr. Herbert Fox, chief of the State Department of Health laboratories at the University of Pennsylvania, was in Lancaster August 18, investigating infantile paralysis.—Dr. Charles Lester Leonard has gone to the International Congress on Radiology

and Electricity in Brussels.—Dr. Edward F. Malone, of the Wistar Institute of Anatomy, has been appointed assistant professor of anatomy in the medical department of the University of Cincinnati, of which Prof. H. M. Knower was recently appointed head.

Bottlers Arraigned.—As a result of the crusade of the State Dairy and Food Commission, a large number of bottlers charged with adulterating soda-water were arraigned August 16. Most of the bottlers entered bail for their appearance in court, which action has led to the belief that saccharin dealers are backing the bottlers and are prepared to finance the fight against the state's charges. The results of the hearings of August 16 were that four men paid fines amounting to \$200 and costs, and nine dealers were held under bail for court. At the hearings August 17, one dealer paid a fine of \$25 and costs and six entered bail for their appearance in court.

City's Milk Supply Inquiry.—Because the large milk dealers have raised the price of milk and insisted that such advance is necessary to insure pure milk, the Bureau of Municipal Research will conduct a thorough investigation of the city's milk supply. This investigation will begin at the source of the supply—the farm—and continue through the handling by shipper and the dealer and its delivery to the consumer. The first bulletin in the inquiry was issued August 18 in the form of a list of fifteen questions to dairymen relating to the conduct of dairy farms and the milking and handling of the product, covering all essential points in the production of clean and sanitary milk.

WEST VIRGINIA

Personal.—Dr. Hugh H. Carr, Fairmont, accompanied by his father, Dr. Lloyd L. Carr, of New York, has just returned from six months' study in the hospitals of Vienna and Berlin.—Dr. Leech K. Cracraft has resigned as city health officer of Elm Grove, and Dr. R. M. Peddicord has been named in his place.

Tuberculosis Sanatorium.—The county commissioners of Ohio County will erect a tuberculosis sanatorium at a cost of \$2,500.—The dispensary of the Antituberculosis League of Wheeling has been opened at 1413 Chapline Street. One of the leading physicians of the city will be in attendance each day. The dispensary now occupies three rooms.

WISCONSIN

Sanitary Drinking Fountains.—The city of Green Bay will abolish the public drinking cup September 1. Sanitary drinking fountains have been erected in the streets and parks of the city.

Personal.—Dr. C. A. Harper, secretary of the State Board of Health and Vital Statistics, is a candidate for the general assembly.—Dr. Frank E. Darling, registrar of vital statistics of the Milwaukee Health Department, has resigned, but has been asked to reconsider his resignation.

Change in Health Department.—The city of Superior, which now employs three physicians to look after the work of the health board, has in view the employment of one man at a sufficient salary to devote his whole time to the work. It is believed that under this plan more efficient work will be done.

Sanitary Homes.—The influence of the crusade of the Antituberculosis Association in this state is seen in the construction of homes. Hundreds of homes built in Wisconsin this year make ample provision for open-air sleeping. Architects and builders have recognized this demand for pure air and plenty of sunlight and have begun designing buildings with this idea in view.

Enlisting the Children in Sanitation.—Health Commissioner William C. Rucker of Milwaukee has introduced the plan of organizing companies of boys and girls of the city to be called the Health Guard, who will be enlisted in the work of keeping the city clean. They will see that back yards and alleys are kept clean and sanitary. The organization will be on a military basis, and daily reports will be made to headquarters, which are to be established in the hall of Lapham Park. Dr. Rucker is to be commander-in-chief of the organization. He will give frequent lectures to the children, instructing them in their work and show disease in its various forms. This follows the plan inaugurated in New York City by Colonel Waring some years ago.

GENERAL NEWS

Intern Wanted for Government Insane Hospital.—The Civil Service Commission will hold examinations October 5, at the usual cities throughout the country, for a medical intern in the Government Hospital for the Insane at Washington, D. C., and for other similar vacancies as they may occur. Positions are held for one year and pay \$50 a month and maintenance. Advancement is possible, with increased pay. This hospital has over 3,000 patients and employees. For several years it has been difficult to secure enough persons to fill these positions, so those who are qualified have a good chance to be successful. Further information may be had from the commission at Washington.

Antirabic Treatment.—Public Health Report of the Hygienic Laboratory of the U. S. P. H. and M.-H. Service for August shows that for the year ended June 30, 1910, 60 patients were treated at the laboratory with antirabic inoculations. Of these, 57 completed the treatment. No deaths were known to have occurred among these patients. Of the 60 patients, 47 were actually bitten or scratched by the teeth of the animal; 10 had scratches or wounds exposed to the saliva, or were exposed during laboratory manipulations. Fifty-five persons were bitten by dogs, 3 were bitten by cats, 1 by a cow, and 1 by a mule. Examinations show that 54 of the exposures were to actual rabies as shown by the laboratory examination. In addition to the inoculations at the laboratory, antirabic treatments were sent out to state boards of health in the form of dried cords preserved in glycerin. This method of transporting the virus a long distance without appreciable loss of potency has been found successful. Nine hundred and fifty-one treatments were thus sent out to state boards in ten different states.

International Medical Association.—The volume of transactions of the fifth annual session of the International Medical Association, Mexico, whose membership is made up, with a few exceptions, of physicians from the United States practicing in Mexico, shows that an interesting meeting was held at Aguas Calientes, January 25 to 27, 1910. About thirty of the seventy-five members of the association were present. Dr. S. H. Hodgson, Tampico, president of the association, presided. Among the foreign physicians present were: Dr. Howard A. Kelly, Baltimore, who read a paper on "Fibroid Tumors," and Dr. John M. T. Finney, also of Baltimore, who took part in the discussions. Dr. Carlos E. Husk, Santa Barbara, was elected president; Dr. R. H. L. Bibb, president-elect for 1911; Dr. F. W. Taube, vice-president; and Dr. J. S. Steele was reelected secretary-treasurer. The transactions contain, in addition to the minutes, papers and discussions, a half-tone picture of the members present at the meeting, some editorial notes, and some poetry. The work of the meeting shows that the Mexican physicians are up to the hour in medical subjects.

Meetings to Be Held in September.—A number of national and state societies are to hold annual meetings next month. Among them are the following:

Amer. Acad. of Ophthalm. and Oto-Laryn., Cincinnati, Sept. 19-21.
Amer. Assn. of Obstetricians and Gynecol., Syracuse, Sept. 20-22.
American Public Health Association, Milwaukee, September 5-9.
Amer. Roentgen Ray Association, Detroit, September 28—October 1.
Kentucky State Medical Association, Lexington, September 28-29.
Medical Society of Missouri Valley, Council Bluffs, Iowa, Sept. 1-2.
Michigan State Medical Society, Bay City, September 28-29.
Mississippi Valley Medical Association, Detroit, September 13-15.
Oregon State Medical Association, Portland, September 7-9.
Wyoming State Medical Society, Casper, September 27.

The fifth annual meeting of the Medical Association of the Southwest will be held at Wichita, Kansas, Oct. 11 and 12. The past meetings of this society have had programs of a high order and as the society has almost nothing of a business nature to come before it the whole session is practically devoted to the consideration of scientific matters. The central location of Wichita, coupled with the fact that the committee promise an unusually good program, should call forth a large attendance of the best men in the district, which comprises Texas, Arkansas, Missouri, Kansas and Oklahoma.

The twenty-third annual meeting of the Medical Society of the Missouri Valley will be held in Council Bluffs, Iowa, September 1 and 2, under the presidency of Dr. A. B. Somers, Omaha. The officers feel that the date is a good one, with prospect of good weather.

FOREIGN

Pellagra in Austria.—The Austrian government has constructed in southern Tyrol six modern steam rye bakeries, which are under the direct supervision of the governor of the province, in order to stop the popular use of infected corn

meal, which is held to be responsible for the pellagra existing in that country. In order to make the rye bread popular with the masses, the authorities have fixed the price at which it shall be sold. The Hungarian government has adopted strict regulations against the sale of corn meal under any other than its own name.

Cholera.—The epidemic of cholera that has prevailed throughout a large portion of Russia seems to be extending in other parts of Europe. A considerable number of cases have been reported from southern Italy, and King Emanuel and Queen Helena are taking a deep interest in the situation. The authorities in Austria and Germany are taking measures to prevent the spread of the disease in their countries, and measures to prevent the introduction of the disease into England have also been the subject of consideration by the British government. The United States government has also given instructions to consular officers at European ports as to the prevention of the embarkation of infected immigrants to this country. During the week ended August 6, 20,468 cases were reported throughout Russia with 8,679 deaths.

LONDON LETTER

(From Our Regular Correspondent)

LONDON, Aug. 13, 1910

The Increase of Lunacy

As shown in previous letters to THE JOURNAL, the number of insane persons in Great Britain, both absolutely and in proportion to the population, has considerably and steadily increased in recent years—a fact which has given much concern to those interested in public health and has been taken by some to be one of the indications of race degeneracy of which much is now written and so little is proved. There is little reliable foundation for these gloomy forebodings. The greater strain on the nervous system produced by civilized life certainly seems to have produced some increase in insanity. What the real increase amounts to is difficult to say, however, for the alarming statistics which are given have to be discounted by this consideration: The number of insane given is based entirely on the number who have been certified and sent to asylums. With the great modern improvement in asylums people are not so loath to send in their friends as in former times. Therefore many are now admitted who would not have figured in the statistics in former times. The sixty-fourth report of the Commissioners in Lunacy, which has just been issued, shows that the number of certified insane under care in England and Wales on Jan. 1, 1910 was 130,553 or 17,666 more than a year previously. This increase may be contrasted with that of 2,703 for 1908, of 2,096 for 1907, and 2,009 for 1906. The average annual increase for the 10 years ending 1909 was 2,394. Thus the increase for the last year was 628 below the average. A better index of the increase of insanity is obtained by comparing the figures with those of the general population. In the past 50 years the number of certified insane has increased by 255 per cent. while the population has increased by only 83.7 per cent. The proportional figures for more recent years are more satisfactory. The estimated population in 1910 is 12.2 per cent. above that of 1900 and the number of insane 22 per cent. In 1909 there was a marked approximation between the two series, the increase of population being calculated to be 1.16 per cent. and the increase of the insane 1.37. Thus, there is a tendency for the two series to meet and the increase of insanity to cease. A cleaner estimate of the growth of insanity is obtained by taking the ratios which the number of insane bear to the total population. On Jan. 1, 1910 the total number of notified insane was 36.1 per 10,000 of the general population. Ten years earlier the figure was 33.06, so that an increase of 9.2 per cent. had taken place in the 10 years. In the last of these years, however, the increase had fallen to 0.22 per cent. Statistics dealing with the causes of insanity are given in tabular form. Of 50 suggested causes, 12 were considered the principal cause in two-thirds of the cases. In their order of comparative frequency they were as follows: (1) the puerperal state; (2) epilepsy; (3) sudden mental distress; (4) alcoholism (the yearly average of admissions in 1907-08 in which alcoholism was the principal cause, was males, 1,589; females, 709); (5) influenza; (6) prolonged mental distress; (7) senility, which often stands alone as the determining condition of dementia; (8) the climacteric in women; (9) congenital mental defect; (10) insane heredity; (11) injuries; (12) syphilis. These 12 causes are therefore regarded as exercising the greatest influence in the production of insanity but in many cases the causation was complex, several causes combining.

The Revision of the Pharmacopeia

The second report of the Committee of Reference in Pharmacy appointed by the General Medical Council contains several important alterations. The names of three preparations have been altered, namely, liquor iodi fortis, liquor magnesi carbonatis, and hydrargyri oleas, respectively to pigmentum iodid, liquor magnesi bicarbonatis, and hydrargyrum oleinum. For the preparation of linimentum hydrargyri the following formula has been substituted as giving more permanent preparation than the official one: mercury ointment, 5; ammonia solution, 4; camphor liniment, 8. The two last are to be shaken together in a bottle and the ointment then triturated with them. To avoid the well-known and dangerous incompatibility of liquor arsenicalis with solutions of alkaloid salts, especially strychnin, with which it is often prescribed, sometimes with fatal results from precipitation of the strychnin and ingestion of the total quantity in one dose, a new formula has been substituted in which the solution is acid. Extractum nucis vomice is still to be standardized to contain 5 per cent. of strychnin, in spite of the Brussels International agreement by which it should contain 16 per cent. of total alkaloids. The specific gravity of ether is to be 0.720 instead of 0.735. On account of being easier to make and being free from objectionable color, a plaster made with atropin sulphate is to be substituted for emplastrum belladonnæ. Extractum hydrastis liquidum is to be standardized.

Fatal Poisoning From the Use of Phenol as a Dressing

Though phenol (carbolic acid) is extensively used in surgery the cases in which poisoning has resulted from its external use are few. An inquest has been held on a girl aged 2 years who was run over by a van and taken to St. Thomas's Hospital with a wound of the leg. The mother was given a lotion of 1 to 20 phenol and was directed to add an equal part of water to it and use the product as a dressing. When she applied the lotion the child screamed. Two days later the child was admitted with symptoms of phenol poisoning from which she died. At the inquest evidence was given that the child was a subject of the status lymphaticus which caused idiosyncrasy to the carbolic acid. The lymphatic glands were four times the normal size and the spleen twice the normal size. The jury returned a verdict of accidental death and did not blame any one.

Decline in the Sale of Nostrums

It is satisfactory to be able to report a slight decline in the sale of nostrums in spite of the tremendous efforts made by their exploiters to push their sale, by lavish expenditure in advertising. Probably an important cause of the decline is their exposure in the book entitled "Secret Remedies" published by the British Medical Association. As nostrums are subject to a duty by the government their sale can be exactly gauged from year to year. The revenue from the stamp duty on them during the year ending Mar. 31, 1910 was \$12,500 less than in the preceding year and \$110,000 less than in the year before that. Their sale, however, is still enormous, as is shown by the fact that the revenue derived from them in that last financial year amounted to \$1,550,000. As the duty on each article of the value of one shilling (about 25c) or under is three half pence (3 cents) it follows that the total number of articles sold must have been about 50,000,000. Taking into account the fact that a considerable proportion cost much more than a shilling, few less, the annual revenue income derived by their exploiters must amount to over \$12,500,000.

The Dangers of Flannelette

The shocking tragedies by which children are fatally injured due to the inflammable nature of flannelette have from time to time been reported in previous letters to THE JOURNAL. A light comes in contact with a child's flannelette shirt or gown and in an instant the child is enveloped in flame and burned to a horrible and usually fatal extent. By impregnating flannelette with certain salts it can be rendered non-inflammable, but the increased cost resulting prevents the poor from buying this article. An important series of tests on the inflammability of certain textiles has been carried out by the British fire prevention committee, which has also made suggestions for legislation on the subject. The test proposed is that a square yard of the material shall be ten times washed with soap and water and ironed. Being then dry, it is suspended vertically from one edge and a standard flame is applied to the bottom edge for from 15 to 30 seconds. If then not more than one-twentieth of the whole area of the fabric is burnt within 60 seconds the material shall be classed as non-flaming. The committee suggests that material which

cannot be so classed shall have woven or printed on every yard of the selva the words "burns rapidly," or, if sold in the form of garments, the words shall appear twice on the principal band or inner hem; that material or garments sold as non-flaming shall be similarly marked with the words "non-flaming;" that any firm selling "union" (a mixture of wool and cotton) or flannelette contrary to these regulations, or selling as non-flaming material which does not comply with the test, shall be liable to prosecution; that parents and guardians shall be specifically responsible for death or injury by fire to children wearing flannelette or union marked "burns rapidly;" and that local authorities shall issue warnings on the subject. The committee found that ordinary flannelette burned with such rapidity that it was often consumed in 60 seconds and was more inflammable after washing than before. Union also proved very inflammable, especially when washed. Flannel and "non-flam" were alike in that they did not carry flame and only the portion within the power of the flame was affected.

Ferro-Silicon*

Ferro-silicon is an alloy made by heating in an electric furnace steel turnings, quartz and coal. The coal reduces the quartz to silicon which then forms an alloy with the iron. Ferro-silicon is used in the manufacture of a certain kind of steel to which it imparts a high tensile strength when present to the extent of rather less than 1 per cent. Owing to ingredients in the substance used in its manufacture the ferro-silicon of commerce gives out highly poisonous gases. Calcium phosphate, which is present in the coal and quartz is reduced to calcium phosphid; arsenic, which is present in both the coal and iron, appears as calcium arsenid. In contact with water or moist air the former gives off phosphuretted and the latter arseniureted hydrogen, both intensely poisonous gases. Phosphuretted hydrogen is fatal if present in so small quantity as 2.5 volumes per 10,000 of air and arseniureted hydrogen is scarcely less dangerous. It is, therefore, not surprising that under certain conditions, as when carried in the cabins of ships, deaths have resulted. But it is only after repeated sacrifice of life that the fact has attracted attention. Some 40,000 tons are annually imported into England from France. The earliest recorded case of poisoning is that of an explosion of iron drums containing ferro-silicon which were brought to Liverpool. A porter was seriously injured, and investigations led to the conclusion that the explosion was due to phosphuretted hydrogen. In January, 1905, during a voyage from Antwerp to New York 50 steerage passengers who lodged over a hold in which ferro-silicon was stored became seriously ill and 11 died. The deaths were certified as due to pneumonia. An official inquiry attributed them to unknown causes, but later a further inquiry revealed the true cause. Many other fatalities have subsequently been recorded on steamers and on canal boats. An exhaustive investigation into the whole subject has been made by Dr. S. M. Copeman under the direction of the British government. He has made the following recommendations which have been adopted by the local government board: 1. Ferro-silicon should not be sent out from the works immediately after manufacture but after being broken up into pieces, as usually sold, should be stored under cover but exposed to air as freely as possible for at least a month. 2. Manufacturers should be required to mark in bold letters each barrel or other parcel with the name and percentage grade, the name of the works, the date of manufacture and the date of despatch. 3. The carriage of ferro-silicon on vessels carrying passengers should be prohibited. When carried on cargo boats it should, if possible, be carried on deck. If it is stored elsewhere the place should be adequately ventilated and cut off by airtight bulkheads from the crew's quarters. 4. Storage places at docks or works should have provision for free access of and be at a distance from workrooms.

PARIS LETTER

(From Our Regular Correspondent)

PARIS, Aug. 12, 1910.

First Meeting of the French Pediatric Association

At the suggestion of Dr. Hutinel, clinical professor of children's disease at the Paris college of medicine, the Société de pédiatrie of Paris some months ago took steps toward the organization of a French and an international pediatric association. The international committee in charge of the organization of the latter met in Paris July 23. The Association française de pédiatrie has just held its first meeting in Paris, July 29 and 30, under the presidency of Professor

* See Editorial in this issue.

Hutinel. Two questions of great importance at present were taken up: (1) the thymus, and (2) cerebrospinal meningitis.

PHYSIOLOGY, PATHOLOGY AND SURGERY OF THE THYMUS

The thymus was the subject of three papers, dealing respectively, with the physiologic functions, the pathology and the surgery of the thymus. Dr. E. Weill, clinical professor of children's diseases at the Lyons college of medicine, who presented the first phase of the subject, concludes that, during extra-uterine life at least, the thymus is not comparable to the glands of ordinary secretion such as the thyroid and the adrenals. There is no evidence that there can be hyperthymic syndromes. All that we know concerning the structure and the functions of the thymus indicates that it is comparable to the lymphatic ganglions. Like the latter (and even more actively) it reacts toward infections and intoxications; and, again like the lymphatic ganglions, it is subject to regressive involution with the progress of age; and the precocity of this regression seems to bear a relation to its great sensitiveness. Dr. Marfan, professor of therapeutics at the Paris college of medicine, considered especially the hypertrophy of this gland among quite young infants and the symptoms on which the diagnosis may be based and those which call for thymectomy. When the diagnosis of hypertrophy of the thymus has been established, mercurial treatment should always be tried. If it fails, the treatment employed in all lymphatic hyperplasias (saline baths, arsenic, iodine, calcium) should be used. The administration of epinephrin by mouth (two to four drops a day) may also be tried. When there are serious complications due to compression, it is necessary to use treatment with more rapid action. If the symptoms do not appear too threatening, one may try to diminish the volume of the thymus by radiotherapy; otherwise thymectomy is the treatment of choice. When the dyspnea and cyanosis are so serious as to forbid recourse to this operation, intubation with as long a tube as possible may be tried; but tracheotomy or a short tube should never be used. If the symptoms are thus improved, one may profit by the amelioration to employ thymectomy.

Dr. René Cruchet, *agrégé* professor at the Bordeaux college of medicine, drew deductions from studies of 77 cases with autopsies. He believes that in acute thymic conditions cases of compression of the trachea by hypertrophy of the thymus are exceptional, and that the volume and the weight of the gland play only a contingent rôle, since glands weighing 2 to 3 gm. may provoke attacks while glands weighing 200 gm. may not. Dr. Cruchet believes that compression of nerves is the most probable cause of thymic disturbances. He remarks that often the thymus is hypertrophied only after respiratory troubles such as croup, pulmonary tuberculosis, pneumonia and bronchopneumonia.

The surgery of the thymus was the subject of a paper by Dr. Victor Veau, surgeon of the Paris hospitals, who believes that the functional results of operation are always encouraging. In the crises of suffocation occurring with a large thymus, operation is urgent and may prevent sudden death. In cases of permanent dyspnea without crises of suffocation, removal of the thymus, while less imperative, is still the therapeutic means of choice. In spasm of the glottis, the propriety of operation is more debatable. It may be considered if the physical signs of hypertrophy of the thymus coexist with the spasm. In a case of this kind, observed by Dr. Veau with Professor Hutinel, the result was decidedly favorable. The effects of thymectomy on thymus stridor have not been so encouraging; often the harsh breathing has persisted after the removal of the thymus. Dr. Veau therefore believes that it is not necessary to remove the thymus when strident breathing exists, but the child should be closely watched. If other symptoms of hypertrophy of the thymus, such as crises of suffocation and permanent dyspnea, appear, thymectomy should be performed immediately. One may promise the parents that the removal of the gland will modify the symptoms, but they should be warned that probably the strident breathing will persist.

CEREBROSPINAL MENINGITIS

In a paper on the bacteriology and epidemiology of cerebrospinal meningitis, Dr. Richardière, physician of the Paris hospitals and Dr. J. Lemaire, former intern of the Paris hospitals, emphasize the dangers from bacillus-carriers, particularly persons with more or less accentuated but sometimes latent, contagious, specific rhinopharyngitis due to the diplococcus of Weichselbaum.

Dr. Moussous, clinical professor of children's diseases at the Bordeaux college of medicine, and Dr. Rocaz of Bordeaux

have studied the clinical manifestations of cerebrospinal meningitis of children and the means of diagnosis. The most important elements of the diagnosis are furnished by the examination of the cerebrospinal fluid, withdrawn by lumbar puncture, by the precipito-reaction of Vincent-Bellot and by the fixation reaction of Bordet and Gengou.

Dr. Netter, *agrégé* professor at the Paris college of medicine, emphasizes the efficiency of antimeningococcus serum, which, injected intraspinally, acts as a true specific. As a rule, Dr. Netter injects 30 c.c. of the Flexner serum in very young children. In serious or very obstinate cases, he goes as high as 45 or even 60 c.c. In order to obtain good results, it is necessary to renew the injections during the first three or four days of the treatment. It is best, moreover, to continue them as long as the cerebrospinal fluid contains meningococci. The greatest number of cures, and the most rapid, are obtained when the treatment is begun early. It is therefore better, if there is the least doubt, to inject the serum after the first puncture without awaiting the results of the bacteriologic examination, which, however, ought to be a guide for further injections. Along with the essential therapeutic agent, the serum, other therapeutic means should not be neglected. Netter particularly advises giving warm baths for forty-five minutes at 39 to 40 C. (102 to 104 F.) three times a day. They have a very appreciable action on the stiffening, the pain, and even on the temperature. Repeated lumbar punctures are very useful, for they ameliorate the painful symptoms by diminishing the tension and removing a certain quantity of pathologic agents and other products of disintegration.

Drs. Broca and Debré of Paris emphasized the surgical aspects of cerebrospinal meningitis, especially the severe pains at the beginning which, in the abdomen, simulate appendicitis and, in the limbs, simulate osteomyelitis.

The Next International Congress of Educational Hygiene

The next International Congress of Educational Hygiene will be held in 1913 in Buffalo, N. Y.

BERLIN LETTER

(From Our Regular Correspondent)

BERLIN, Aug. 4, 1910.

Personal

July 30 Professors Senator and Olshausen, who are resigning on account of advanced age, delivered their farewell lectures. Both addresses were transformed into ovations for the retiring scientists. Especially at the lecture of Senator, Prof. Kraus took the opportunity to emphasize the great importance of the investigator. There is no question that the fame of the Berlin university will be lessened by the departure of these two learned men, for their successors cannot fill their places and give no promise of ever equalling their predecessors. Prof. Franz has been called to succeed Olshausen; he is a former assistant of Bumm.

Professor Rubner has been chosen as rector of the Berlin university for the next student year. This is the seventeenth time that a medical man has been accorded this especially honorable position and among the present force belonging to the university a worthier representative could scarcely have been chosen, for Professor Rubner may well be considered as at present the most important member of the university faculty.

Professor Stock of Freiburg has been appointed director of the eye clinic at Jena in place of Professor Wagenmann.

Professor Payr has been nominated as successor to Professor Krönlein, the well-known director of the surgical clinic in Zurich.

Professor v. Eicken, formerly for many years assistant of Professor Killian, now assistant of Professor Siebenmann in Basel, has been called to succeed Professor Leutert as director of the ear clinic at Giessen.

No Trade Tax on Physicians and Lawyers

In Prussia and in most of the other German states, physicians and lawyers are exempt from tax for carrying on their business on the ground of the provision of the law that professions which are not followed merely for commercial purposes but from ideal interests shall be exempt. In the effort at tax reform which is being made in the deeply involved duchy of Hesse-Nassau the effort is being made by some parties in opposition to the program of the government to remove this special privilege of physicians and attorneys. Fortunately it has been possible for the threatened professions to avert the blow. The Hessian legislature (*Landtag*)

has recently decided that physicians shall be exempt from the trade tax as formerly.

Tuberculin Treatment in Rudolf Virchow Hospital

A separate ward in the Rudolf Virchow hospital has been set apart, the same as last year, by order of the city government, for tuberculin treatment, to be conducted by the institute for infectious diseases under the leadership of its director, Dr. Gaffky. Robert Koch had charge of this work formerly.

Communication of Infection by Eggs

Interesting experiments have been made by the imperial health office to determine the ways in which disease may be conveyed by eggs. The infection of hen's eggs with germs may occur by the contamination of the ready formed egg by germs which are either on the outside of the shell or in some cases may penetrate the shell into the egg itself. Micrococci and non-motile organisms appear not to possess this property of penetrating the shell under ordinary circumstances so long as the egg is kept dry. The principal source of the germs in normal eggs is an infection during their formation; 54 per cent. of the eggs investigated contained germs. The communication of disease by eggs may occur either from the germs on the shell or from those contained in the egg itself. In the transmission of disease by germs, the ability of the germ to resist external influences, such as drying, is of great importance. This method of dissemination of chicken cholera is of minor importance. Paratyphoid bacilli remain viable on egg-shells for 10 days and longer and they may also penetrate the shell into the egg itself. For this reason it is not impossible that, exceptionally, hen's eggs may be the source of a paratyphoid infection of man.

Separation of the Medical Bureau from the Department of Education

The much-discussed question of separating the medical bureau from the department of education on account of the overloading of the latter is finally settled. Next April the bureau will be transferred to the department of the interior. As some important branches of the public-health service are now placed in this department (especially the offices of the sanitary police), it is to be hoped that by the consolidation of the entire medical administration in the department of the interior an effective organization of Prussian sanitation will be secured. The conduct of medical instruction naturally remains with the department of education. The minister of education has also the right to confer the title of professor on practicing physicians on account of scientific attainments, although the medical press has repeatedly and justly protested against this practice.

Operation to Prevent Gangrene of Extremities

Some years ago Professor Wieting of the Güllane Hospital in Constantinople reported two cases in the *Deutsche medizinische Wochenschrift* in which he had succeeded in preventing a threatened gangrene of the extremities in consequence of arteriosclerosis by transplanting the femoral artery into the femoral vein. Professor Bier recently reported a similar success at a meeting of the Freie Vereinigung der Chirurgen Berlins. In a man of 38, with gangrenous ulcers on one foot, due to arteriosclerosis from tobacco, Bier performed Wieting's operation in place of the amputation which the patient desired. The immediate success of the operation was very remarkable. The intense pains disappeared and the limb, which had been in some places pale, in others blue and cold, became red and warm and the ulcers dried up. As the report was made only twelve days after the operation, the permanent results are doubtful. However, according to Bier's opinion it may be hoped that, even if amputation should become necessary, the improved nutrition of the leg would permit a lower amputation. Professor Payr reported a similar case in the Greifswald Medical Society. After transplanting the deep femoral artery into the femoral vein in a man of 70 with arteriosclerotic gangrene of the great toe and heel of one leg, the leg remained better nourished for eleven days, but after that the circulation failed and the patient died from heart failure after a few days. This case was unfavorable on account of the severe infection already present. In discussing the prognosis of such operations in threatened arteriosclerotic gangrene and in general in threatened obstruction to the arterial circulation, Payr recommended to choose the deep femoral, as at its point of origin its lumen is nearly the same as that of the femoral artery, and this leaves the arterial circulation in the femoral intact, while in case the femoral artery is used, thrombosis occurring at the point of

suture cuts off at one stroke the blood supply to the entire limb. Severe infection is a contraindication. Venous thrombi present in the inflamed territory would lodge in the peripheral vessels and cause a complete obstruction of the already imperfect circulation. The return of the arterial blood may be successfully carried on through anastomoses of the deep with the subcutaneous veins. According to anatomical and experimental investigation so far made the valves form no objection to the operation.

New Electric Aid to Hearing

At one of the last sessions of the Berlin Otologic Society Dr. Flatau reported investigations which he had made at the Charité ear clinic with apparatus in which the microtelephonic system is applied. In a certain number of cases, in which all other aids to hearing were unsuccessful, success could still be obtained with this system. But in other cases even this apparatus failed because of the inconstancy of its action and of faulty selection. Flatau therefore had new models constructed in which the tuning of the microphone has been tested for a year and the microphone is installed in a specially arranged and peculiarly constructed sound receiver which possesses various arrangements for regulation. Five types are constructed which differ in the arrangement and size of the acoustic aids in the microphone. In the following discussion it was asserted by all that they had had no favorable results from the microphone apparatus so far in use. Although, as is well known, many people who are hard of hearing can hear well through the telephone, the electric hearing apparatus generally gives no better results than an ear tube. It is generally agreed that a functional examination of the patient must be made before the use of such an apparatus. Further trials of Flatau's instrument will show whether it is more effective than the electric apparatus heretofore in use.

VIENNA LETTER

(From Our Regular Correspondent)

VIENNA, Aug. 8, 1910.

Glanders in the Austrian Army

The Austrian army was expected to hold its annual maneuvers as usual in the month of August, but for some time rumors have been afloat that, owing to some disease in the stables, the actual time of the maneuvers was rather uncertain. Meanwhile a serious outbreak of glanders was conceded by the authorities, and although all the extensive preparations pertaining to the housing and boarding of over 130,000 men and 10,000 horses for three weeks were finished, at the very last moment the maneuvers had to be postponed indefinitely; they will not take place this year. This is due to the action of military medical men, whose influence and opinion in these matters had enough weight to overthrow the optimistic view of purely military persons. The disease had been imported, as could be ascertained by the very close investigation, only seven weeks before, and had at first appeared very insidiously, not having been recognized at once. Only after a few soldiers too had become affected was suspicion aroused, and soon bacteriologic evidence was present.

The course of the disease was mild at first but later all the horses attacked succumbed to the disease, and later on all the affected horses were killed. No less than thirteen regiments are suffering from it, and although official data are not given—all things pertaining to military service are guarded here with secrecy—yet the fact that the maneuvers had to be abandoned, although the emperor himself was to have viewed them, allows one to judge the extent of the epidemic. Up till now, with very few exceptions, no human cases in the present outbreak have been dealt with in the experiment laboratories. Every precaution has been taken to prevent the spread of the epidemic to rural households and farms, and to date no cases have been reported from non-military sources.

Ehrlich's Preparation in Austrian Hospitals

Professor Ehrlich's much spoken of preparation "606" is now in use all over the continent and much comment and perhaps too optimistic expectations are attached to it. The lay press in this country has made very commendable efforts to warn the public of the necessity of waiting further effects of the famous remedy. Just in time a report from the dermatologic clinic in Prague was published, in which it was stated that very unpleasant symptoms (blindness, loss of patellar reflexes, severe pain, etc.), similar to those from acute poisoning with methyl alcohol, have been observed after the injection; though the report was somewhat modified afterward, still it had the beneficial effect of restraining somewhat

the enthusiastic expectation of the multitude of syphilitics. On the other hand many favorable reports have been already published by competent observers in the clinics in Vienna, Budapest, Innsbruck and Graz. As is only natural, all their reports emphasize the necessity of watching the patients thus treated for a prolonged period. But the tendency in this country is in favor of this new remedy. It is estimated that the yearly expenditure of the state for the consequences of syphilis in this country, treatment of acute manifestations in the hospitals, as well as of recurrences, housing of the tabetic, the insane and their offspring is at least \$6,000,000, without counting the loss of national property due to the same source. The interest with which further developments are awaited can thus be readily understood.

Decrease of Meat Consumption.

The report of the superintendent of the general market, who has control also over all the other markets in this country, shows, that in 1909 a marked decrease of the consumption of meat was the leading feature of the meat markets. Thus the average meat consumption per year at Vienna has grown from 64 kilos (130 pounds) for each adult in 1898 to 74 kilos (152 pounds) in 1908; in 1909 the figure was 72 kilos, a decrease of 4 pounds. The growth of meat consumption had been very steady and constant. The sudden drop is explained by the difficulty in obtaining the necessary quantity in the face of the increased expenditure for the other absolutely necessary articles of food, which have become so much dearer. In fact, living having become dearer in this country by 40 per cent., especially since 1908, the effects on public health of the existing conditions have been a matter of serious consideration of the responsible government. The deterioration of the quality and quantity of food consumed by the majority of the population has as yet no marked effect on the vital statistics, but unless it is speedily remedied, serious consequences are sure to follow, for the vegetarian diet is also too dear for the laborer, and abstinence from meat alone is not possible or satisfactory.

Marriages

NORRIS S. McDOWELL, M.D., to Miss Mathilde J. McCrystal, both of Philadelphia, August 6.

MARTIN P. SUMMERS, M.D., to Miss Elizabeth Humphreys, both of Cushing, Iowa, July 29.

S. J. NEWTON MAGWOOD, M.D., to Miss Maude McLain, both of Toronto, Ont., July 23.

HOMER G. ROSENBERGER, M.D., Whittier, Cal., to Miss Fay West of Oskaloosa, Iowa, July 14.

WILLIAM CANTINE GILLEY, M.D., to Miss Margaret Jenkins, both of New York City, August 11.

Deaths

Walter Keeler Scofield, M.D. College of Physicians and Surgeons, New York City, 1868; a member of the American Medical Association; and Association of Military surgeons of the United States; of Stamford, Conn.; medical director with rank of rear admiral, U. S. Navy, retired April 28, 1901 after thirteen years sea service and eighteen years and eleven months shore or other duty; who entered the naval service in July, 1861, as assistant surgeon; was commissioned surgeon, June 19, 1866; was commissioned medical director in 1889; and was retired on October 8, 1901; died at his home in Stamford, August 5, aged 71.

Benjamin Horning Detwiler, M.D. University of Pennsylvania, Department of Medicine, 1855; a member of the American Medical Association; one of the founders of the Williamsport, Pa., Hospital, and a member of the medical and surgical staff from its foundation; a trustee of the Danville State Hospital, and at one time president of the board; died at his home in Williamsport, August 9, from paralysis, aged 78.

Frank Stillman Raymond, M.D. Louisville, (Ky.) Medical College, 1875; a member of the American Medical Association; formerly president of the Shelby County (Tenn.) Board of Health and president of the Memphis Board of Health; mem-

ber of the State Board of Medical Examiners; died at his home in Memphis Tenn., August 16, from Hodgkin's disease, aged 57.

Robert A. Jamieson, M.D. University of Pennsylvania, Department of Medicine, 1866; a member of the American Medical Association; emeritus professor of materia medica and clinical medicine in the Detroit College of Medicine; a member of the medical staff of Harper's, St. Mary's and St. Luke's Hospitals, Detroit; died in that city, August 9, aged 66.

Eric A. Davidson, M.D. Bennett College of Eclectic Medicine and Surgery, Chicago, 1898; Rush Medical College, Chicago, 1901; a member of the Illinois State Medical Society; professor of medicine in Bennett College of Eclectic Medicine and Surgery, Chicago; died at the home of his brother in Berkeley, Cal., July 30, aged 51.

Alexander Thompson Bull, M.D. New York University Medical College, New York City, 1848; a member of the Medical Society of the State of New York; died at his home in Buffalo, August 15, from the effects of injuries received by a fall a few weeks before, aged 83.

Wiley W. Tarter, M.D. College of Physicians and Surgeons, Baltimore, 1908; of Mellen, Wis.; died at St. Joseph's Hospital, Ashland, Wis., August 11, from injuries received by the explosion of a barrel of alcohol at Mellen the day before, aged 27.

Mann Page, M.D. University of Virginia, Department of Medicine, 1897; house surgeon and physician to Orange Memorial Hospital, Orange, N. J., died suddenly at his home in Keswick, near Cobham, Va., July 29, from dysentery, aged 40.

Eugene T. Wilhelm, M.D. Jefferson Medical College, Philadelphia, 1878; a member of the Medical Society of the State of Pennsylvania; and Lehigh Valley Medical Association; died at South Bethlehem, June 24, from diabetes, aged 61.

David William Rees, M.D. California Eclectic Medical College, Los Angeles, 1890; for many years a druggist and physician of Needles, Cal.; died at the California Hospital in Los Angeles, July 31, from septicemia, aged 41.

Seymour J. Holley, M.D. College of Physicians and Surgeons, New York City, 1857; a veteran of the Civil war; for twelve years an inspector on the Brooklyn Board of Health; died at the Brooklyn Hospital, August 7, aged 73.

James W. Nance, M.D. Baltimore University School of Medicine, 1894; a member of the Medical Association of the State of Alabama; died suddenly at his home in Russellville, August 5, from heart disease, aged about 55.

George Charles McIntyre, M.D. University of Toronto, Faculty of Medicine, Toronto, Ont., 1906; of St. Mary's, Ont.; died at the Royal Victoria Hospital, Montreal, Que., March 6, from tuberculous spondylitis, aged 28.

William J. Foley, M.D. Louisville (Ky.) Medical College, 1897; a member of the Kentucky State Medical Association; health officer of Fayette county; died at Lexington, August 7, from paralysis, aged 36.

William Henry Hull, M.D. Harvard Medical School, Boston, 1865; a member of the Massachusetts Medical Society; a veteran of the Civil War; of Holbrook, Mass.; died at Essex, Mass., August 8, aged 78.

Edmund Livingstone Moodie, M.D. Hahnemann Medical College, 1903; a member of the American Medical Association; of Chatham, Ohio, died at Harper Hospital, Detroit, July 8, from sepsis, aged 35.

Oliver J. Mayne, M.D. Denver (Colo.) College of Medicine, 1890; a member of the American Medical Association; formerly mayor of Como, Colo.; died at St. Luke's Hospital, Denver, August 9, aged 47.

Francis Emory Ross, M.D. College of Physicians and Surgeons, New York City, 1870; a member of the Missouri State Medical Association; died at his home in Springfield, August 8, aged 72.

George Herbert Huntington Redding, M.D. Bellevue Hospital Medical College, New York City, 1887; died at his home in San Francisco, Cal., August 8, from cirrhosis of the liver, aged 52.

Samuel B. Bailey, M.D. Eclectic Medical College of Pennsylvania, Philadelphia, 1859; a retired practitioner of Higganum, Conn., died at his home in that place, August 11, aged 84.

Samuel H. Griffin, M.D. Missouri Medical College, St. Louis, 1880; a member of the American Medical Association; died at Humansville, Mo., April 7, from pneumonia, aged 61.

William Francis Lynch, M.D. Cooper Medical College, San Francisco, 1882; a member of the Medical Society of the State of California; died at Hayward, Cal., July 1, aged 55.

Samuel B. Littlepage, M.D. College of Physicians and Surgeons, Keokuk, Iowa, 1885; a retired practitioner of California; died at a hospital in Oakland, August 11, aged 72.

Levi Spencer Wilcox, M.D. Long Island College Hospital, Brooklyn, N. Y., 1873; twice mayor of Champaign, Ill.; died at the California Hospital, Los Angeles, August 5, aged 63.

James Robert Crockett, M.D. University of Maryland, School of Medicine, 1891; of Burkes Garden, Va.; died at the University Hospital, Baltimore, August 2, aged 54.

John Wesley Klein, M.D. Hahnemann Medical College, Philadelphia, 1871; died suddenly at his home in Louisville, Ky., August 13, from cerebral hemorrhage, aged 59.

Martin Luther Fittro, M.D. University of Maryland, School of Medicine, 1896; died at his home in New Martinsville, W. Va., August 12, from uremia, aged 45.

James H. Scarborough, M.D. Medical Department of the University of Nashville, Tenn., 1872; died at his home in Tharpe, Tenn., August 9, aged 72.

Thomas R. Young, M.D. Jefferson Medical College, Philadelphia, 1859; died at his home in Ashland, Ky., August 2, from senile debility, aged 77.

William C. Baylor, M.D. Washington University School of Medicine, Baltimore, 1869; died at Willow, Cal., June 27, from cerebral hemorrhage, aged 67.

Mark C. Ott, M.D. University of Alabama Medical Department, 1900; died at his home in Greensboro, Ala., July 2, from tuberculosis, aged 34.

Alexander G. Carroll, M.D. Georgia College of Eclectic Medicine and Surgery, 1894; died at his home in Atlanta, Ga., August 7, aged 53.

Randolph S. Steensen, M.D. University of the South, Medical Department, Seawanee, Tenn., 1900; died at Harrisburg, S. D., August 9, aged 38.

William Ross, M.D. Eclectic Medical Institute, Cincinnati, Ohio, 1845; died at Wilton Junction, Iowa, August 1, from heart disease, aged 82.

Charles E. Fay, M.D. Detroit Medical College, 1877; died at his home in Kalamazoo, Mich., August 3, from disease of the liver, aged 56.

Henry T. McNatt, (license, Ark., 1903); formerly of Buena Vista, Ark.; died at his home in Stephens, Ark., August 9, aged 37.

George Alfred Rogers, M.D. St. Louis Medical College —; died at White Lake, S. D., April 18, from nephritis, aged 60.

Henry G. Groff, M.D. Philadelphia Medical College, 1853; died at Harleysville, Pa., July 28, from uremia, aged 80.

J. N. Houston, (License, Tenn., 1889); died at his home near Parsons, Tenn., August 6, aged 84.

Good Pamphlets on Tuberculosis.—Public Health Bulletins 35 and 36 are authoritative monographs on the subject of the nature, prevention and climatic treatment of tuberculosis, which will be serviceable for the information of the physician himself or to place in the hands of patients. They are written by Passed Assistant Surgeon F. C. Smith, of the U. S. Public Health and Marine-Hospital Service. Bulletin 35 gives in plain language the ascertained facts regarding the nature, contagious character, mode of spread and practicable means of prevention of the disease. Useful hints and advice to patients are appended. The information in this pamphlet will not be new to physicians but is given in an excellent form for the instruction of the general public. The second pamphlet is more especially designed for the guidance of the physician in selecting a suitable climate and in deciding whether climatic change is desirable. The opinion of a number of experts is quoted and the different circumstances affecting the decision of the medical adviser are carefully pointed out, it being especially emphasized that the decision must be made with reference to the special circumstance of the individual case. A list is given of the most healthful and suitable places in the different states as shown by the location of state sanatoria, also a list of places characterized by high altitude and dryness and a list of places at more moderate or low altitudes which are suitable for climatic treatment.

Correspondence

Patenting Instruments and Apparatus

To the Editor: A word by way of protest against the patenting of newly devised surgical instruments and apparatus by physicians. It has long been held that any improvement in the armamentarium of the physician should be given to the profession for the benefit of the sick and afflicted. For a physician to patent a method of laboratory technic or apparatus whose purpose is to aid in the diagnosis or prevention of disease is no worse from an ethical standpoint than the patenting of a surgical instrument.

The argument that the physician should profit in this way from his ingenuity and knowledge is fallacious. Otherwise the most laudable efforts of present-day medicine, the prevention of disease, should have no legitimate place in the physician's work.

A most glaring example of this evil has been the recent exploitation of a set of instruments for perforating the skull, which have been patented. They have been widely advertised under the name of the inventor, a doctor, both by the medical press and by circular letter. The claim made for them that it is impossible to injure the underlying dura or brain is not true, as I have demonstrated to my satisfaction. The price, \$50, is four or five times their intrinsic value. For \$2.40 I have obtained a set of perforating instruments at a local hardware store which answer every purpose—and they are just as safe.

JOHN D. SINGLEY, Pittsburg, Pa.

Registration of Foreign Physicians

To the Editor:—Having read the letters of Drs. Hoenes and McReynolds in THE JOURNAL on this subject, I beg leave to make a few remarks. By way of criticism I will add that there was an air of sentiment about them that interested me. If candidates for license to practice medicine in Canada will comply with the various provincial laws, they will have no difficulty. Of course, if one has, up to a few years ago, carried the hod and later, by way of recreation, obtained a degree or license to practice medicine either by serving apprenticeship for a year as office boy to some poorly trained practitioner, or attending one, two, or even three, five or six-month courses at some diploma mill, one will be blocked at the start. I am surrounded by physicians who have spent, at most, two six-month terms at college, hardly enough time to digest a part of one of the primary subjects of medicine. Did these latter, in the obscurity of the barnyard, obtain a knowledge of anatomy (comparative or human) or did they get their knowledge by inspiration? I have met them at different state board examinations, and later heard of their having passed successfully; all I can say is that they would not have been qualified to take a professional examination in Canada. In conclusion, permit me to say that if a physician has the qualifications which are exacted of all nationalities in Canada, he can obtain the license to practice there.

D. NATHAN, Norristown, Pa.

Doctors of Public Health

To the Editor:—Apropos of the editorial in THE JOURNAL, August 20 on this subject, may I not ask your attention to the course which since 1906 has been offered by the University of Pennsylvania, and which is outlined in the special advertisement of this school in the same number of THE JOURNAL? Dr. Harold Wood, who graduated this spring in this course, has very recently been placed in charge of the Mississippi State Laboratory by the Board of Health of Mississippi.

ALLEN J. SMITH, Dean.

Miscellany

The Mesocelic Recess in Man and its Relation to Reissner's Fiber.—Reissner's fiber, a small bundle commencing in numerous fibrils from the ependymal groove of the lower vertebrates and passing downward or backward through the iter, the fourth ventricle and the central canal of the cord to its posterior extremity, has been traced as a constant structure in the vertebrates from the lamprey up to the monkey. Its function has been supposed to be nervous, but this has not been demonstrated; and Horsley has found that it does not degenerate like a nerve with electrolytic lesions. Dendy has recently (*Nature*, Dec. 23, 1909) suggested that it has a mechanical function in regulating flexure of the body. It seems to be highly elastic and normally under considerable tension during life, as it is found retracted and twisted up after section of the cord. In a recent communication to the Royal Society (June 2, reported in *Nature*, June 9), Professor Dendy and G. E. Nichols report the finding of a rudimentary structure in the human brain corresponding to the ependymal groove, or as they prefer to call it, the subcommissural organ, from which this fiber starts. In the human fetus it consists of two bands of highly columnar epithelium with deeply situated nuclei, invaginated posteriorly into the roof of the iter to form a "mesocelic recess" as in certain lower vertebrates. In the adult brain this is represented by a small cavity lined with characteristic columnar epithelium imbedded in the roof of the iter at the back of the posterior commissure, and in close relation to another cavity, apparently representing a communication with the lumen of the iter. In the fetus this communication is widely open. It is not probable, they say, that any trace of Reissner's fiber will be found in the human adult, as with the loss of the tail and assumption of the erect position, the function it is assumed by them it would have, of automatic regulation of the flexure of the body, is no longer needed, and is represented only by the vestigial remnant of the subcommissural organ.

Paraffinomas.—This term has been coined by Delangre to describe the inflammatory lesions and tumefaction liable to develop around a deposit of paraffin injected into the subcutaneous cellular tissue. The "beauty specialists" have taken up this method of improving the appearance of their customers and serious results have sometimes followed. In one such case presented at a recent meeting of the Paris Dermatologic Society, Thibierge presented a young woman who had been given by a local beauty specialist a number of injections of hard paraffin to remedy a very slight depression in the nose. The immediate results were so satisfactory that she had her face all gone over in this way, 80 injections being made in the course of 21 months. A year later the various deposits became the seat of disfiguring swelling, the aspect suggesting pronounced leontiasis. There is no pain except from the stretching of the skin. Operative removal of the paraffin seems to be the only resource in this case, electrolysis, heat and massage offering little prospect of success with the hard paraffin. Gaucher reported a case in which the paraffinomas had developed in the breast of a young woman and they were followed by cancer. Pautrier also reported 4 cases of paraffinomas in the face, the work of a "beauty specialist;" in one case the lesions ulcerated. He found that each deposit of paraffin was walled in with connective tissue. Balzer called attention to the frequent development of subcutaneous fibromas in the tuberculous after injection of paraffin with a low melting point. Injection of paraffin into a cavity, to replace a testicle, for instance, seems harmless, but the anatomic conditions in the subcutaneous tissue are very different and the results are liable to be deplorable.

Concussion of the Brain.—E. Schwarz discusses a number of cases of trauma causing concussion of the brain, his article appearing in the *St. Petersburg med. Wchnschr.*; 1910, xxxv, 267. His experience shows that an apparently slight accident may induce a focal injury of the brain which yet causes no symptoms and the patient feels no ill effects. The focal lesion may be revealed, however, by blood in the cerebrospinal fluid or a serous effusion may follow if the focus does not heal soon,

the cerebrospinal fluid then showing increased pressure or other changes. Lymphocytosis may reveal the changes resulting from the focal lesion. With rest, healing is soon complete, but the necessity for rest from the first should be emphasized even though the patient may feel entirely well. Without rest the pathologic condition may persist and the clinical picture of meningitis be presented in time. The euphoria may be pronounced after lumbar puncture; the latter is especially valuable in these cases. The euphoria is in marked contrast to the condition in cases of traumatic neuroses.

Idiosyncrasies.—R. M. Beauchant concludes an article on this subject in the *Progrès Médical*, April 16, 1910, with the statement that the different idiosyncrasies should be considered as having a common etiology and clinical kinship. Certain families are especially subject to them, although they may appear in various forms in the same person and in the same family. They are generally associated with symptoms which should be regarded as of the same pathogenic importance; these include urticaria, acute edema of the skin or mucosa, asthma, all of which generally accompany the idiosyncrasies; with, more rarely, stenosis, migraine, eczema, pruritus, dysmenorrhea and certain forms of chronic rheumatism and, invariably, with an extreme tendency to nervousness. He thinks that a common soil is evident in all these manifestations, a tendency to instability on the part of the vasomotor apparatus, an angioneurotic diathesis, and that certain features indicate a thyroid origin for the various disturbances noticed with this diathesis.

Congenital Scoliosis.—A case of congenital scoliosis is reported by Frederick Langmead, (*Proc. Roy. Med. Soc.*, May, 1910), in an infant aged 10 months, who was brought to the hospital for "projection of the back." There was a pronounced spinal curvature with the convexity to the left, most severe in the dorsolumbar region. In the upper dorsal and lower cervical region was a compensating curve in the opposite direction. The curvature was irreducible. Rickets could be excluded. A skiagram revealed an extra bone between the last dorsal and first lumbar vertebra, wedge-shaped; with the base of the wedge to the left. The bone bore two transverse processes at its base and one at its apex, and thus apparently represented a vertebra and a half. That the twelfth dorsal vertebra was not included in this bone is shown by the fact that twelve ribs could be counted on each side, the lowest of which joined the vertebra above. There were five lumbar vertebrae plainly visible below.

The Diagnosis of Cholera in the Philippines.—Erroneous diagnoses have been responsible for the failure to destroy foci of cholera infection in the city of Manila, according to Victor G. Heiser, Director of Health (*Quarterly Report of the Bureau of Health, Fourth Quarter, 1909*). In the last quarter of 1908, 129 cases of meningitis were reported to the health authorities. In order to verify the diagnosis in a number of these cases autopsies were made, and these showed that the cause of death was cholera and not meningitis. In view of this, it was decided to hold autopsies in all cases reported as meningitis. This had the effect of increasing the diagnostic acumen of those signing death certificates and in the subsequent quarter only 34 cases of meningitis were reported. Twenty-eight of these were autopsied, and only 2 proved to be meningitis; 17 were cholera; 4 were beri-beri; 1 was empyema and 4 were undetermined. In the last quarter of 1909 there were 151 deaths from cholera in Manila. The total death-rate in Manila for 1909 was 35.50 per 1,000, as against 47.62 per 1,000 in 1908.

Carcinoma in Early Life.—Howard T. Karsner (*Proc. Path. Soc., Philadelphia*, February, 1910) reports a series of ten cases of carcinoma, seven occurring, respectively, at the ages of 7, 10, 11, 14, 19, 21 and 22, and three at the age of 23. Five were in males and five in females. The duration of all the cases had been short, confirming the opinion of other observers that cancer runs a much more rapid course in childhood and early life than in adult life. From Karsner's experience and from a study of the literature in early life the sexes seem to show equal predisposition to cancer, the intestine and skin being especially subject to cancer in boys, and the ovaries in girls.

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS will not be noticed. Every letter must contain the writer's name and address, but these will be omitted, on request.

RESTRICTION OF USE OF RED CROSS—SUBSTITUTES THEREFOR

To the Editor:—Can you give me information about the restriction of the use of the red cross? Would the green cross be a proper insignium to be put on physician's automobiles in order to secure from the police exemption from the speed ordinance in emergency cases? LOUIS F. ROSS, Richmond, Ind.

ANSWER:—The Geneva Convention in 1864, and later in 1906, adopted an international agreement providing that the "emblem of a red cross on a white ground and the words 'Red Cross,' or 'Geneva Cross' should be adopted by all nations participating in the convention as a special designation in times of peace or war to protect or to designate sanitary formations and establishments, the personnel and material protected by the convention." The American National Red Cross, which comes under the regulations of the International Geneva Treaty, was granted a charter by Congress, Jan. 5, 1905, authorizing it to act in behalf of the United States in matters of relief under the treaty. The executive committee of the American National Red Cross then requested all hospitals, health departments and like institutions to refrain from the use of the red cross in order to avoid confusion and suggested as a substitute some other insignia such as a green St. Andrew's cross on a white ground. Congress at its last session restricted the use of the red cross to the American National Red Cross. This law, of course, only prohibited organizations from adopting this emblem after the passage of the law. Although the American Medical Association has used this badge for many years and does not come under the provisions of the law, it was felt by many that the use of the Geneva red cross should be restricted to the American National Red Cross. Consequently, at the Atlantic City Session in 1909 a committee was appointed to submit designs for new insignia. The report of this committee was presented at St. Louis (See THE JOURNAL, June 18, 1910, pages 2068 and 2081). The green St. Andrew's cross on a white ground would be a proper badge for physicians' automobiles, hospital ambulances, etc., and could be adopted by agreement with authorities.

The Public Service

Medical Department, U. S. Army

Changes for the week ended August 20, 1910.

Casaday, George H., dent. surg., August 9, granted leave of absence for twenty days, to take effect about August 10, 1910.
Cole, Clarence L., capt., August 8, designated for duty with troops from Whipple Barracks, Arizona, Camp Atascadero, California.

Rutherford, H. H., major, August 13, ordered to Fort Totten, N. Y., for duty.

Ford, Joseph B.; Van Dusen, James W., majors, August 13, report en route to Camp of Instruction at Fort Riley, Kansas.

Fletcher, John P., lieutenant, August 13, left Fort D. A. Russell, Wyoming, for duty at Camp E. S. Otis, Wyoming.

Holmberg, Carl E., lieutenant; Kremers, Edward D., lieutenant; Hathaway, Levy M., capt.; King, Charles T., lieutenant, August 10, ordered to Camp of Instruction at Atascadero, California, for duty.

Nelson, Kent, capt., Aug. 15, 1910, on arrival at San Francisco will proceed to Whipple Barracks, Arizona, for duty.

Carpenter, Alden, dent. surg., August 15, returned to West Point, N. Y., from leave of absence.

Farrow, Edgar J., M. R. C., August 15, now at Vancouver Barracks, Washington, having completed the duty assigned him, will proceed to Fort Morgan, Alabama, for duty at that post.

Leslie, Samuel H., dent. surg., August 15, ordered to proceed from his home, Monticello, Kansas, to Fort Leavenworth, Kansas, for duty at that post.

Yemans, Herbert W., M. R. C., August 15, having reported in this city in compliance with orders heretofore issued, is designated as the representative of the War Department at the International Esperanto Congress.

Shaw, Henry A., major, August 15, relieved from duty at Fort Slocum, N. Y., September 1, and will proceed to Boston, for duty as attending surgeon. Major Shaw is relieved from duty at Boston, and will proceed at the proper time to San Francisco, and take transport to sail from that place about Dec. 5, 1910, for duty in the Philippines Division.

Jenkins, F. E., M. R. C., and Fuller, Major Leigh A., August 13, report arrival at Camp of Instruction, Fort Riley, Kansas.

Keller, William L., capt., August 14, left West Point, N. Y., on detached service, accompanying the First Class, Corps of Cadets, to Fort Hancock, N. Y.

Bell, Leonard P., M. R. C., August 16, reports for duty at Camp of Instruction, Fort Riley, Kansas.

Cullem, Charles W., M. R. C., August 16, granted leave of absence for two months, to take effect upon his arrival in the United States.

Brechemin, Louis, col., August 16, granted leave of absence for four months, with permission to go beyond the sea.

Church, James R., major, August 16, granted leave of absence for one month, to take effect upon his relief from duty at Fort Robinson, Nebraska.

Nichols, Henry J., capt., August 16, on arrival at New York City, will proceed to Peoria, Illinois, for the purpose of studying pellagra in connection with the commission organized by the governor of Illinois.

Brechemin, Louis, Jr., capt., August 16, leave of absence extended one month.

Le Wald, Leon T., capt., August 17, leave of absence extended one month.

Medical Corps, U. S. Navy

Changes for the week ended Aug. 13, 1910.

Lumsden, G. P., medical inspector, detached from the recruiting station, Chattanooga, Tenn., and directed to wait orders.

Tolfree, H. M., passed asst.-surgeon, detached from the naval recruiting station, Cleveland, Ohio, and ordered to the naval recruiting station, Chattanooga, Tenn.

Orders issued by Commander-in-Chief of Asiatic Fleet:

Ames, M. H., passed asst.-surgeon, ordered to duty at the naval hospital, Olongapo, P. I.

Higgins, S. L., passed asst.-surgeon, detached from Mohican and ordered to the *Nie Yark*.

Dollard, H. L., asst.-surgeon, detached from the *Relief* and ordered to the *Charleston*.

Guest, M. S., surgeon, ordered to the navy yard, Pensacola, Fla., when discharged from treatment at the naval hospital, Las Animas, Colo.

Fitts, H. B., medical inspector, detached from the navy yard, Pensacola, Fla., and ordered to Washington, D. C., for examination for retirement.

Tolfree, H. M., surgeon, commissioned surgeon from March 24, 1910.

Allen, A. H., passed asst.-surgeon, detached from duty with the naval rifle team of 1910 and ordered to duty at the naval hospital, navy yard, New York, N. Y.

Higgins, S. L., passed asst.-surgeon, commissioned passed assistant surgeon from November 12, 1909.

State Boards of Registration

COMING EXAMINATIONS

IOWA: Capitol Building, Des Moines, September 12-14. Sec., Dr. Guilford H. Sumner, State House.

MASSACHUSETTS: State House, Boston, September 13-15. Sec., Dr. Edwin B. Harvey.

MISSOURI: Capitol Building, Jefferson City, September 20-22. Sec., Dr. Frank B. Miller.

NEW YORK: Albany, September 27-30. Chief of Examinations Division, Dr. Charles F. Wheelock.

Arkansas Homeopathic May Report

Dr. P. C. Williams, secretary of the Arkansas Homeopathic Board of Examiners, reports the written examination held at Texarkana, May 18, 1910. The number of subjects examined in was 12; total number of questions asked, 120; percentage required to pass, 75. The 8 candidates all passed.

College	PASSED	Year Grad.	Per Cent.

Book Notices

INTRODUCTION TO THE ANALYSIS OF DRUGS AND MEDICINES. An Elementary Handbook for the Beginner. By Burt E. Nelson, Chemist to the New York State Hospitals. First Edition. Cloth. Price, \$3 net. Pp. 384, with 31 illustrations. New York: John Wiley & Sons, 1910.

In view of the extremely diversified nature of the substances entering into the composition of medicines, the separation and determination of the several ingredients of a medicinal preparation is often a matter of great difficulty and is occasionally impossible. Since a glimpse into nearly every phase of chemical activity is necessary in order to cope successfully with all of the problems met with in drug analysis, a comprehensive work devoted to the subject is a much-sought desideratum. Because of the magnitude of the task no one has hitherto attempted the preparation of such a treatise, but the "Introduction to the Analysis of Drugs and Medicines" apparently is a step in this direction, although this work, as the title implies, is little more than an outline of the subject. At the outset of the book the term "drug" is limited by definition to "a dried plant part in the crude state." In the early chapters attention is called to the apparatus and operations used in the ultimate analysis of inorganic and organic substances and the outlines of the principal methods used in elementary qualitative and quantitative analysis are given. A chapter is devoted to the determination of molecular weights, common radicles and chemical formulæ. The general principles of drug analysis, by means of which the proximate principles of drugs may be separated and identified, are given in some detail. While not so comprehensive as the section devoted to microscopic drug analysis (in which field the author is more at home) this is in some respects the most valuable portion of the book.

The analytical scheme outlined is an eclectic adaptation of the earlier schemes described by Dragendorff, Parsons and other writers. While it is clear, concise and usable, its chief value is in calling the attention of the beginner to the principal factors to be kept in mind and the results to be expected in drug analysis, leaving the details to be obtained from the teacher or from specialized works of reference. Brief sections are devoted to the assays of chemicals, crude drugs and pharmaceutical preparations and a short chapter is allotted to pharmacologic methods. Many valuable tables are given in the appendix. As no diagnostic methods are given, the book can have no place in the curriculum of the medical school nor in the working library of the physician. It should prove useful in those schools giving elementary courses in drug analysis, and particularly in those in which but little time can be given to foundation courses in analytic chemistry.

THE PRODUCTION AND HANDLING OF CLEAN MILK. Including Practical Milk Inspection. By Kenelm Winslow, M.D., M.D.V., B.A.S. (Harv.), Chairman of the Committee on Milk of the Washington State Medical Association. And Essentials of Milk Bacteriology. By H. W. Hill, M.D., Minnesota State Board of Health Laboratories. Cloth. Price, \$3.25. Pp. 367, with 101 illustrations. New York: W. R. Jenkins Co., 1910.

An attempt is made in this book to treat the bacteriology, chemistry, physiology of milk, also the practical points of caring for cows, construction of stables, handling of milk, milk transportation, and the inspection of milk and dairies. In addition, the bacteriologic examination is discussed, with a chapter devoted to the identification of bacteria usually found

in milk and the preparation for culture media. Finally a series of laboratory experiments is outlined for the practice of students, by Prof. H. W. Conn. All these subjects cover a rather large field and could be treated more successfully in single books each devoted to one subject specially. If the author had confined himself to the practical parts of milk production and the handling of milk the value of the book would have been enhanced.

The first chapter deals with germs in their general relation to milk. Aside from the fact that many misstatements, contradictions, inaccuracies and some typographic errors have crept in, it must be confessed that the composition is not always clear and leaves doubt in the mind of the reader of the position actually taken by the author. For instance, after discussion of pasteurization, parts of which are useless repetitions, it remains problematic whether the author is in favor of pasteurization or not. To mention some of the inaccuracies: It is stated that bacteria multiply by spores. This is difficult to conceive in view of the fact that a bacterium, as far as we know, never produces more than one spore. The discussion on the germicidal action of fresh milk is premature, since investigators are by no means agreed on the subject. The same comment applies also to the presence of "natural ferments" in milk.

Chapters 2 to 8 are devoted to practical questions of the production, handling and transportation of milk; also the care of cows, the food and the construction of stables. These chapters are of great merit, although occasionally not quite clear and consistent, and they might have constituted the most profitable nucleus for a book of this nature. The chapter on the housing and care of cows is perhaps the most valuable in the book. Milk inspection is discussed in Chapter 9. The presentation of this subject is fair and complete on the whole.

Chapters 10 and 13, on the bacteriology of milk, are written by Dr. H. W. Hill. Justice to this large subject cannot be expected in a limited space, but the information given is fair and clear, although somewhat from a one-sided point of view. Chapter 14 contains instructions for laboratory work. As stated before, this belongs properly in a special work and really has no place in this book.

In the appendix we find illustrations of modern sanitary cow-stables. Unfortunately, the most approved modern swinging stanchion is omitted, and the statements in regard to milking machines are rather premature.

ESTÉRO-COLITE: ESTOMAC ET SYSTÈME NERVEUX. Par le docteur L. Pron, Membre adhérent de la Société de médecine de Paris. Paper. Price, 2 francs. Pp. 132. Paris: Jules Roussel, 1, Rue Casimir-Delavigne, 1910.

The author sustains the proposition that the condition commonly known as membranous colitis or colitis mucosa is closely connected with nervous dyspepsia and with enteroptosis. He regards the intestinal condition as directly dependent on the failure of the stomach to perform its functions, and therefore directs his therapeutic measures to the cure of the fundamental affection. He attributes the influence of the stomach in producing the pathologic condition of the intestine to the irritation of the solar plexus which is set up by abnormal gastric conditions, is transmitted to the intestinal plexus, and thus causes the intestinal symptoms. The chapter on therapeutics includes a consideration of the dietetic and physical measures suitable to the cure of the dyspepsia as well as to the medicinal treatment. The importance of psychotherapy is recognized. The treatment appears to be in accordance with the methods usually followed in the treatment of these affections. The emphasis which the author puts on the connection of intestinal symptoms with a gastric disorder which is sometimes unrecognized is suggestive and gives to the book its *raison d'être*.

ARBEITEN AUS DEM PHARMAZEUTISCHEN INSTITUT DER UNIVERSITÄT BERLIN. Von H. Thoms, M.D., Professor und Direktor des Pharmazeutischen Institutes der Universität Berlin. Volume VII. Comprising work of 1909. Paper. Price, 7 marks. Pp. 312, with illustrations. Vienna: Urban & Schwarzenberg, 1910.

The present volume follows much the same lines as the previous ones. We note with regret the statement in the preface that Dr. Zernik has left the service of the institute. He is succeeded in these investigations by Dr. E. Richter.

Much of the report is taken up with the investigation of some comparatively rare plants, especially some of the essential oils. A large section is given to the investigation of foodstuffs from the German colonies. Notwithstanding the great importance of the investigations reported, it is to be regretted that so much of the material is of no immediate practical value to the physician.

DIE PRAXIS DER HYDROTHERAPIE UND VERWANDTER HEILMETHODEN. Ein Lehrbuch für Aerzte und Studierende. Von Dr. A. Laqueur, leitendem Arzt der hydrotherapeutischen Anstalt und des mediko-mechanischen Institutes am städtischen Rudolf-Virchow-Krankenhaus zu Berlin. Price, 8 marks. Paper. Pp. 288, with 57 illustrations. Berlin: Julius Springer, 1910.

This book reflects the present teaching of hydrotherapy in Germany and Austria, where the practice of this important branch of therapeutics has reached a high degree. The first chapter takes up the physiologic action of hydrotherapy and thermotherapy and includes a good description of the "reaction." Other chapters deal with the influence on the blood, the secretions, the nervous system and the musculature. This is followed by section on the general technic and the application of hydrotherapeutic measures in various diseases. Electric baths, including the "four-cell bath" and electric light treatment, are well illustrated.

Medicolegal

Skill and Care Required of Specialists, Particularly Hernia Specialists—Liability for Bad Results—New and Unaccepted Methods of Treatment—Paraffin Treatment of Hernia

The St. Louis Court of Appeals says, in the malpractice case of McClarin vs. Grenzfelder (126 S. W. R., 817), that, as treatment for hernia, the defendant, on January 6, injected into the plaintiff's right groin over the hernia some aseptic paraffin. The theory of the practice was that this paraffin, after it was injected into the middle of the muscle outside the abdominal cavity and the peritoneum, would form into a compact mass over the hernia, and close, and hold closed, the orifice in the peritoneum so the bowel could no longer protrude, or possibly hold the bowel in place until the orifice had contracted enough to prevent protrusion. But, notwithstanding the plaintiff was pronounced cured, he said that he suffered pain from that time until May 7, when he was taken to a hospital, found to be suffering from peritonitis, and was immediately operated on therefor.

Taken in its entirety, the testimony of the one expert introduced by the plaintiff pointed rather weakly to the conclusion that the paraffin in the abdominal cavity caused the peritonitis. Doubt, however, was cast on this theory by the paraffin not being in contact with the peritoneum, and the complete cure of the peritonitis before the paraffin was removed. Moreover, the injection of it, if a regular and approved method of treating the ailment, would not necessarily lay the defendant liable, even if it induced the peritonitis, for untoward results sometimes follow the most scientific surgery. On the whole, more evidence on the main issues of fact was desirable; but, as there was proof that the peritonitis might have been caused by the wax, and some evidence tending to prove the injection of it was not a right way to treat hernia, the court indorses the submission of the case to the jury, which returned a verdict in the plaintiff's favor for \$2,000 damages. At the same time, the judgment is reversed, and the cause remanded for another trial, on account of erroneous instructions given the jury.

The theory carried through the instructions was that the defendant was only required to possess and exercise the skill and care exercised by physicians of ordinary skill and ability in localities like St. Louis, whereas this court thinks he was bound to exercise the care of a specialist, and that the propriety of his treatment was to be determined with reference to the practice and approval of specialists. It might be that the system was recognized, approved, and used by physicians who had kept pace with scientific progress in

relieving hernia, but "was a method or manner of treatment not used by physicians and surgeons of ordinary care and skill," as the instruction read.

Because the defendant held himself out as an expert in the treatment of hernia, the law required him to treat the plaintiff with the skill and care commonly shown by physicians and surgeons in St. Louis and cities in advance or abreast of it in the practice of medicine and surgery, who devote special study to the treatment of the disease; that is to say, the proficiency and skill of hernia specialists, not meaning by this designation only physicians who treat that disease exclusively, but also those who by special study and experience probably have acquired more accurate knowledge of the right methods of treatment than is possessed by general practitioners of medicine. And in ascertaining whether the requisite skill and care were employed in a given case, contemporary knowledge of the ailment and how to relieve it are considered.

If expert practitioners of the defendant's school concurred in opinion about the right method of treating hernia, and the defendant adopted a method not recognized as sound, then, according to courts which have passed on the question, his conduct should be regarded as an experiment which rendered him liable if it injured the plaintiff in the way alleged; that is, caused peritonitis. But if the defendant's system of treatment was recognized as proper, then, though there were other systems recognized as proper, he could not be convicted of negligence if he made use of the one he deemed most suitable for the plaintiff's case. In such a condition of medical science the question of the defendant's responsibility would turn on whether he administered the remedy preferred by him with the degree of care and skill required of a person holding himself out as an expert.

What the court is dubious about is whether the evidence for the defendant conduced to prove the treatment he used was recognized by experts of his school (the allopathic or regular school) as proper for the relief of hernia. That it was of comparatively recent origin ought not, by that fact alone, to put it in the class of innovating experiments, so as to lay the defendant liable for a bad result, even though he displayed reasonable skill and care in the manner of applying it. This is true because some of the most approved systems of treatment, like antitoxin for diphtheria, met with general acceptance by the medical profession a few years after their discovery.

Importance to Public Health of Pure Milk and Validity of Law Fixing Standard

The Supreme Judicial Court of Massachusetts says, in *Commonwealth vs. Wheeler* (91 N. E. R., 415), that milk is a very important article of food, which enters largely into the sustenance and development of children. It is the natural food of infants for a considerable time after their birth, and the milk of the cow is often used to supply the deficiency of milk from the mother. Probably there is no other article of diet the purity and good quality of which are so important to the life and health of the people, and especially to the life and health of the young children, as are the purity and good quality of milk. It is also very easy to adulterate it, and it may be adulterated, especially by the addition of water, in such a way that nothing but a chemical analysis will detect the adulteration.

The legislature, in the interest of public health, has enacted laws intended to enable the people to obtain milk of good quality, that is free from adulteration. No one can question the propriety of legislation on this subject. If statutes are directed to this end, the methods adopted for accomplishing the object desired, so long as they have some manifest relation to the object, must be left to legislative determination. Not only in Massachusetts, but in several other states, the establishment of a standard founded on the quantity of milk solids and of fat contained in the milk has been adopted as the best way of preventing adulteration, and of securing for purchasers milk whose quality can be relied on. It is a familiar exercise of the police power for the prevention of fraud and promotion of the public health.

That the defendants did not know that the milk they had for sale contained less than the prescribed quantity of milk solids, or but 11.65 per cent. when 12.15 per cent. of milk solids were required by the statute, was immaterial. It has often been decided that, in the public interest, the burden of ascertaining at his peril, whether an article that he sells is within the prohibition of a criminal statute, may be put on the seller.

The defendants offered evidence that the milk in their possession was not deleterious or injurious to health, but was nutritious and beneficial as an article of food. This, if proved, would not have shown that the law requiring milk sold or for sale to contain at least 12.15 per cent. of milk solids and not less than 3.35 per cent. of fat was invalid. The fact that a certain kind of milk is not injurious to health, and that it is somewhat nutritious and beneficial, as an article of food, if used discreetly, with full knowledge of its qualities and deficiencies, is not enough to deprive the legislature of its power to forbid the sale of it, if it would be likely to be used to commit frauds on purchasers who might buy and use it, relying on its supposed possession of a larger proportion of nutritious qualities, and if such use of it would be likely greatly to injure the public health, and particularly the health of young children. The legislature might believe that the authorized sale of such milk would open so wide a door to the commission of frauds on the community, and would be so injurious in its consequences, that such sales should be prohibited.

The offer to prove that the milk was without adulteration, and just as it came from properly fed cows in sound health, was governed by the same considerations.

2. Mental Disease.—The majority of the real diagnostic difficulties uncovered by Southard's analysis would appear

to require more intensive work in the field of clinical pathology. For such work in psychopathic hospitals this paper is an appeal.

3. *Dementia Præcox*.—The topographic study of dementia præcox brains, both gross and microscopic, is commended as likely to shed new light on the pathogenesis of certain symptoms, notably paranoid and katatonic symptoms.

4. *Mental Disease*.—In these 10 cases the diagnoses made from the morphologic findings were changed in 2 cases after comparison with the clinical histories. One was due to the fact that the psychosis, a delirium, resulted from a functional stomach disorder that could not be recognized post-mortem; the other was a case in which the brain of a patient with dementia præcox had undergone certain senile changes. Of the clinical diagnoses, on comparing with the morphologic, one was corrected, and 2 left unclassified were in a measure cleared up. Counting the unclassified as errors, there were 3 errors in the clinical diagnoses of these 10 cases. Of these, one was due to the poor histories and inability to communicate with the patient; one was probably due to the fact that the patient died the same day that he was admitted; and one error was made because enough importance was not assigned to the disturbance of bodily functions as a causative factor in mental disease. Errors are liable to occur, then, in both the morphologic and clinical diagnoses of a case, but when the 2 are compared it is believed that fairly accurate conclusions may be reached.

6. *Thyroid Gland in Mental Disease*.—Fifty patients were examined. Excluding a case of exophthalmic goiter and one of acromegaly, about 77 per cent. of the Danvers' series show changes. A possible relation between the thyroid gland and the process of emaciation is seen in the fact that 64 per cent. of the subjects with "normal" thyroids (11) had become emaciated under hospital or other conditions, whereas none of the individuals with chronic thyroiditis (12) showed emaciation. Again, only 13 per cent. of the subjects showing follicular or interstitial excess of colloid had become emaciated, so that the question arises whether such histologic "excess" means excess or means defect in thyroid constituents in the body at large.

Though the pulse had not been intensively studied clinically in these cases, certain data are available. None of the "normal" thyroids had been associated with pulse-rates over 100 (75 per cent. under 90). Only 1 of 7 cases of marked chronic thyroiditis yielded a pulse over 90 (but that one over 120). The exophthalmic goiter patient naturally had a high pulse; the acromegaly patient a low one. The hyperplastic and excess-colloid cases, as well as those of slight chronic thyroiditis, are variously distributed with respect to pulse. Five descriptions of thyroid glands in dementia præcox are added; 3 of these yielded both microscopic and macroscopic alterations (one enlarged, 2 small), which may or may not signify important alterations in the amount of thyroid products reaching the circulation. Two cases of briefer duration showed neither microscopic nor macroscopic alterations.

7. *Heart Disease in Acute Psychosis*.—This study of the incidence of heart lesions in acute psychoses is based on the protocols of cases autopsied over a period of 30 years. The protocols are unselected, and are those of such autopsied cases as possessed clinical histories permitting the diagnosis of manic-depressive insanity or dementia præcox. This study showed that the percentage of hearts probably normal functionally is higher in manic-depressive insanity than in dementia præcox; dilatation of heart occurs more frequently in manic-depressive insanity than in dementia præcox. Leaving out dilatation of the heart, the incidence of every cardiac lesion in dementia præcox is greater than the incidence of the corresponding lesion in manic-depressive insanity. The incidence of individual heart lesions is relatively greater in the acute psychoses than in all psychoses combined, except that the relative frequency of hypertrophied hearts in manic-depressive insanity is below the average. This study suggests the desirability of a close clinical study of hearts, pulse and blood tension in the group of acute psychoses.

8. *Bacterial Invasion of Blood and Cerebrospinal Fluid*.—The material was unselected, save (1) that cases without

readily palpable nodes were not examined; and (2) that 30 of the 50 cases gave macroscopic signs of intestinal disease of greater or less severity (15 from an epidemic of bacillary dysentery). There were no detectable differences in the proportion of bacteria growth at different intervals post-mortem. Positive cultivations were obtained in (a) cerebrospinal fluid, 85 per cent.; (b) blood, 80 per cent., and (c) node, 78 per cent. Growths from all 3 regions were obtained in 55 per cent. Growths from 2 out of 3 regions were most frequently obtained in cerebrospinal fluid and lymph node (17 per cent.). The incidence of various organisms was as follows: Cocci in the blood, 20 cases; in the cerebrospinal fluid, 22; and in the lymph node, 16; *staphylococcus aureus* in these sources, 5, 6 and 3 cases, respectively; streptococci, 2, 1 and 0 cases; bacilli in 1, 8 and 10 cases in the respective source. The findings seem consistent with the hypothesis that in the terminal exhaustions of the insane bacterial invasions are almost the rule.

14. *Autocathorosis Sinus Thrombosis*.—Sims presents a study of a case of extensive sinus thrombosis of the cerebral sinuses. It is of interest because of the extent of the thrombosis and the slowness of its development; also because of the probable origin in a focus of sclerotic vessels in one of the lateral sinuses. A rugged, healthy man of 49, with history of frequent severe headaches for a year, had an attack of sudden onset with violent headache and vomiting lasting over 12 hours. Periods of somnolence, aphasia and increasing weakness of the right side followed, with temperature chiefly subnormal. Later hallucinations, delirium, hemiplegia, deepening stupor and coma appeared, with death at the end of 6 weeks. The case was clinically doubtful. The most likely diagnoses made in life were brain tumor, apoplexy and meningitis. The true diagnosis of sinus thrombosis was not seriously thought of by any of the physicians dealing with the case in life. The symptom most characteristic of sinus thrombosis was missing, i. e., congestion of the veins of the cranium and face.

15. *Fractured Skull*.—This case illustrates a curiosity in the diagnosis of skull fracture, based on the finding of brain material in the gastric contents. A car conductor sustained a fracture of the skull from collision with a telegraph post while on the running board of his car. Two hours after the accident, the patient showed an obvious depressed fracture of the right frontal bone, and while on the accident table began to vomit bloody fluid. The vomiting was extensive (1 to 6 oz.) and lasted 8 hours. At the third or fourth attack of vomiting, a bit of material was observed on the blanket which macroscopically suggested fresh brain tissue. This suggestion was later microscopically confirmed. The patient died 65 hours after the accident. He spoke no words while in the hospital, but was restless, spontaneously arising from bed, was without paralysis and would resist attempts at examination (such as gagging of mouth or lifting of eyelids) by incoordinate movements of arms and legs. On gagging he uttered long, loud, ah-sounds. Later he groaned, habitually breathed through the mouth and a few hours before death became cyanotic. There was no systematic examination of reflexes. The knee-jerks were neither markedly decreased nor increased. The pupils were moderately and equally dilated.

- 29 *Aerotherapy. J. G. Sauer, New York.

22. *The Problem of Race Betterment*.—Mears believes that we should endeavor to secure, not only sterilization, but also removal of the sexual desire. He advocates for this purpose

the operation of ligation of the spermatic cord, which sterilizes and removes sexual power and desire after a period of a few months. The operation of resection of the vas deferens sterilizes, but leaves sexual desire, and this both injures the defective individual and causes him to continue in his bad practices.

29. **Aerotherapy.**—Sauer proposes that we shall sleep in beds that are so arranged that the head projects out of the window in all weathers. This induces good sleep and good health. To secure this he removes the legs of the head of the bed to the middle of the side frames, so that the head may be pushed out of the window, and the window shut on to the lower portion of the body, the upper part projecting out of the window; it should be well protected by a hood and warm bedding in winter.

32. Abstracted in THE JOURNAL, May 28, 1910, p. 1817.

34. **Singultus Gastricus Nervosus.**—As a condition, Bassler says, this is rarely encountered (seen by him in only two cases of several thousand neurotic stomach conditions), and most probably usually in well-nourished young adults and most often in the female. The close study of these two cases in the way of heredity, past history, cause, imitation, syphilis, hemorrhages, infectious diseases, chemical toxic causes (lead, alcohol, tobacco), and the usual symptoms of hysteria were not present, and both of them had a *bona fide* gastric hyperesthesia accompanying them. The most careful examination in both failed to elicit any skin anesthesia, hyperesthesia, or paresthesia, had pain, emotional crises, were mentally excitable or depressed or had loss of emotional control, were impulsive, had spinal or vertical pains, globus hystericus, vasomotor disturbances, disturbed sleep, somnambulism, or cerebral automatism, paralysis, contractures, tremor, ataxic or choreic movements, absence of skin reflexes, complete loss of concentric limitation of the visual field or disturbance of color sense, manifested the presence of hysterogenic zones, pseudoangina, amyosthenia, constipation, and other of the less common clinical symptoms observed in the more or less irregular course of hysteria. Both the patients were exhaustively examined by competent specialists, among whom were neurologists, ophthalmologists, gynecologists, and others, and both were considered as normal in all other respects, and Bassler therefore believes that such a neurotic condition of the stomach does occur, the cause of which is primarily situated in that organ, and that this gives rise to involuntary contractions of the diaphragm as a reflex manifestation.

37. **Syphilis of the Innocent.**—A number of cases are cited by Brouner in support of his contention that syphilis, one of the most contagious infections afflicting mankind, is undoubtedly on the increase as judged by hospital and private practice, and that many estimable, respectable people acquire this disease innocently, and for a long time are unaware of the real nature of their illness. These innocent victims innocently infect others, and the most frequent source of infection is by using public drinking cups, public towels in bathrooms and improperly washed cooking utensils, etc. Brouner would prohibit the practice of passing around drinking water in public places of amusement because of the danger of infection that lurks in them. Hospitals, dispensaries and public buildings, he declares, should not be provided with public drinking cups, but with individual paper cups. The public should also be instructed as to what to demand from their dentists in the way of aseptic instruments. It is too common a practice for dentists not to pay any attention to the advances made in knowledge of asepsis.

- 39 Abdominal Pain: Its Clinical Significance. G. Eusterman, Rochester, Minn.

38. **Flexner's Antimeningitis Serum.**—From a limited experience with the use of Flexner's serum, White concludes that it may be difficult or impossible to find Gram-negative intracellular cocci in the exudate in certain cases of infection with *Diplococcus intracellularis meningitidis*. This is especially true in a severe, almost fulminant, type, and this experience has been reported by other observers. In the presence of positive symptoms of meningitis and with the absence of an etiologic factor, such as pneumonia, endocarditis, or injury, and when the fluid removed is cloudy, giving positive evidence that a meningitis exists, White says the serum should be used as though the presence of *Diplococcus intracellularis meningitidis* was proved, until such time as cultures or other evidence reveals the nature of the infection. It is advisable to adopt this attitude only when one has had experience with meningitis, sufficient to make him sure of his ground, and it is only the occasional case in which one will need to wait for the results of culture before making a positive diagnosis. Additional encouragement to the use of the serum in a case where one must wait for the results of culture before making certain diagnosis is afforded by marked improvement in the condition of the cerebrospinal fluid.

80. Metastasis of Carcinoma in the Ovaries.—An examination of 15 cadavers by Rosenstirn showed that carcinoma in the abdominal cavity may cause an implantation metastasis in the cul-de-sac of Douglas. It occurs earlier than that of the ovaries. It is influenced in its origin by the law of gravity and therefore affects first the deepest part of the pouch. It is not necessary in these cases that the primary carcinoma has perforated into the free abdominal cavity—a sarcoma still entirely covered by serosa can cause implantation by metastasis in the cul-de-sac of Douglas. Rosenstirn emphasizes that it should be recommended in radical operation of carcinoma of the organs in the abdominal cavity to remove the deepest situated part of the Douglas cul-de-sac, i. e., the pouch.

81. Trauma in Production of Pelvic Diseases.—Among the last 1,000 cases of railway accidents that have come under Harris' personal supervision 412 were women, and of this number 77, or 18.7 per cent., claimed injury to the pelvic organs as a direct result of the accident. In 24 patients a miscarriage resulted. The youngest woman was 20 years old, and had already had two children. The oldest was 49 and had also had two children. It is interesting to note that in

all but one of the patients, the miscarriage occurred before the fifth month. It is perfectly plain, says Harris, that many of the conditions found, namely, old lacerations, rectocele, cystocele, prolapses, old displacements, intraligamentous cysts, pelvic tumor, etc., bore no causal relation to the accidents; on the other hand, it is equally plain that a ruptured extrauterine pregnancy, an acute volvulus, a twisted pedicle of the ovarian tumor, a pelvic hematoma, the miscarriages, etc., were the direct result of the accidents. The chief question is whether intrapelvic diseases such as salpingitis, metritis in its various forms, displacements of the ovaries and uterus, etc., can be caused or initiated by such accidents as have been described above.

Of much interest and importance in this connection is the married or single state of the women. Of the 412 women injured, 331 were married and 81 single. Of the 76 women claiming some form of injury to the pelvic organs (eliminating the one who merely injured the vulva by sitting down on her heel) 72 were married and 44 were single, but of these 4, 3 were single in name only, as one was pregnant at the time, two showed unmistakable signs of marital relations, and one of these had an old infection. One only was actually a miss and the only pelvic disturbance she had was a slight irregularity of menstruation for 2 or 3 months. Of the married women 22 per cent. claimed injury to the pelvic organs while of the actually single only 1 per cent. had a temporary disturbance of menstruation. The inferences to be drawn from these facts are, that women with normal, healthy pelvic organs very rarely, indeed, have these organs injured by such accidents as described, while those whose organs have been damaged by the violence of parturition or from the effects of previous infections, may have former symptoms temporarily aggravated or acute exacerbations of an old infection.

84. Abstracted in THE JOURNAL, July 9, 1910, p. 160.

85. Vasomotor Relations of Shock.—Seelig and Lyon's work points, in every instance, against the correctness of the theory that shock is a symptom complex due primarily to vasomotor exhaustion.

87. Abstracted in THE JOURNAL, June 4, 1910, p. 1891.

88. Traumatic Injuries of the Lungs and Pleura.—This is an exhaustive experimental study which cannot be presented in abstract in the limited space at our disposal.

89. Liver Abscess.—Dudley has treated several hundred cases of amebic dysentery since 1899, by both the colonic irrigation treatment and the ipecac method, and has found the latter treatment to be more prompt and sure in its effects. The ipecac treatment he found prompt and efficient. If instituted at an early stage, the patient does not have to be confined to home or hospital for more than 5 or 6 days and the treatment seldom needs to be repeated unless there has been a reinfection. The method of administration of ipecacuanha, with some important modifications, is that described by Manson. A preliminary dose of castor oil and laudanum is given and the patient put on a milk diet. After abstaining for 4 hours from both food and water, 2 grams of ipecac are given, in 6 pills, with just as little water as possible. The patient must lie on the back in bed, in a dark room, and should not be allowed to talk or be in any way molested. No food or liquid should be taken for 8 hours after taking the medicine. After the 8 hours are up the patient may take milk and water liberally until 4 hours before the time for the next dose. Dudley usually has the patient fast from 4 p. m. and gives the pills at 8 p. m. In this way food may be taken during a good part of the day. If the pills are so made that they will pass out of the stomach without dissolving, the preliminary dose of tincture of opium and the mustard plaster to the stomach may be dispensed with without fear of nausea. If at any time nausea should occur, an ice bag about the throat gives most relief. Grams 1.650 are given on the second day; 1.325 on the third; 1.0 on the fourth; 0.650 on the fifth, and 0.325 on the sixth day. The patient is now put on light diet and a 0.325 gm. pill is given for 6 days longer, when the cure is usually complete, although in some cases it may be necessary to continue for 12 days.

In this method of administration the making of the pills is a very important matter, Dudley says. The pill mass is best made with the extract of glycyrrhiza. The pills are then coated heavily with salol or enclosed in kreatinized capsules. If kreatinized capsules be not at hand the pill mass may be put in the ordinary gelatin capsules and the space between cover and body of the capsule sealed with a little liquid gelatin. The capsules are then placed in a Petri dish and a few drops of formalin are put in a dish so as not to touch the capsules. The cover is then placed on and allowed to remain for about 8 hours. The capsules should be exposed to the air for 6 or 8 hours before use as otherwise they will prove irritating to the stomach. This method of treatment has proved of value in the catarrhal, bacillary, amebic and balantidium forms of dysentery and in diarrhea.

91. Abstracted in THE JOURNAL, Jan. 22, 1910, p. 315.

92. Closing Incisions in Renal Pelvis.—For some years past Kelly has been in the habit of utilizing, in closing the renal pelvis, the lamella of Gerota's fascia (fatty capsule) which spreads out over the posterior surface of the kidney as well as its pelvis. The tissue of the pelvis *per se* affords no satisfactory secure hold for sutures closing an incision made, say, in extracting a calculus, but when this fibrous capsule is caught and sutured as an additional layer overlying the pelvis proper the whole is bound securely together and such a wound rarely leaks. Another valuable use of this fascial layer is in plication of the hydronephrotic pelvis. It is here the firm hold for the needle is secured in passing from the margin of the kidney where the fascia is unusually strong down toward the ureter and back again to the margin in the form of the letter V.

93. Operation for Cystocele.—The operation described by Graves aims to reduce the two component parts of the cystocele in such a manner as to restore the anterior wall to its natural contour and to eliminate all irregularities and protrusions which may impinge on a snugly repaired perineum. The operation as it is now performed by Graves, is somewhat less complicated than formerly described, but the essential principle is the same.

97. A New Uterine Forceps.—The uterine forceps devised by Schoenberg is to be used for the purpose of operating on the tubes, ovaries or round ligaments. The jaws are covered with rubber tubing.

107. Flexner's Antimeningitis Serum in Meningitis.—To date, the serum has been used in 38 cases, in nearly all of which Brown has seen the patient at least once. There have been 12 deaths, or a mortality of 30 per cent. Of the deaths, 1 occurred in an epidemic where the serum gave out, after decided improvement of the patient from its use; 4 patients were moribund when injected; 1 patient got streptococcus infection of the spinal canal (relapsed case); 1 died of acute diffuse myelitis after 7 injections; 2 patients were treated entirely by other physicians, with meager directions, and no complete data of the result was ever furnished Brown. Two of the 9 occurred in an epidemic on Goat Island, 1 a fulminant case, after a single injection of 2/3 the present dosage; and 1, a recurrent case, 6 weeks after the first attack in which the disease was probably very diffusely spread over the meninges. There have been 2 relapses in the 38 cases, both patients dying. Neither was so promptly treated in the relapse as in the first attack.

111. Skin Diseases in the Hawaiian Territory.—Some dermatoses, according to Alderson, are modified not by the heat of the sun, but rather by some other effects of its rays. In the Hawaiian Territory senile keratoses, various other pre-epitheliomatous conditions, basal cell epithelioma and cutaneous neoplasms in general are extremely rare. It cannot be denied that the sun's beneficent rays are a factor here also. In such a uniformly warm climate as that of Honolulu, the skin is naturally more or less hyperemic, and moist most of the time. It is due to this state of affairs that the use of the Roentgen ray demands extreme care and vigilance, for under these circumstances radiodermatitis develops very easily, as was proved in a number of cases in which exposure was not unduly prolonged (as measured by standards elsewhere) and severe burns resulted.

122. Varieties of Poliomyelitis.—In McClanahan's opinion all cases of poliomyelitis may be grouped under five heads, spinal, bulbar, meningeal, polyneuritic and abortive. His experience includes a study of 45 cases; about 15 of the patients he saw during the acute stage in consultation with other physicians, while the others were examined after recovery from the acute symptoms. In all cases he had a good, clear, clinical history, and many of the patients he has had opportunity of seeing a number of times. The ordinary or spinal type is the form of poliomyelitis as described by Charcot. In the bulbar type there is an involvement of the nuclear centers in the medulla oblongata. McClanahan saw 4 cases of this type, all being fatal. In one there was paralysis of the facial nerve and in another, paralysis of the motor nerves of the eye, without the face being involved. By the meningeal type is meant that in which the onset is characterized by meningeal symptoms, fever, pain, often headache, neck rigidity and more or less unconsciousness. Indeed, some of these cases in the beginning are so similar to epidemic cerebrospinal meningitis, that the physician may easily make such a diagnosis. McClanahan saw one case that from the symptoms was typical of meningitis, and but for the presence of poliomyelitis in the vicinity he would have made this

diagnosis. But in that case a lumbar puncture with a clear fluid, and the subsequent history, established the fact that it was not a true meningitis but a meningeal type of poliomyelitis.

In the polynuritic type of cases there is generally hyperesthesia, with suffering and sometimes intense, agonizing pains, usually in the lower extremities or in the back. McClanahan saw one such case. The pains in the back and extending down the left leg were so intense that for several days it was necessary to keep the child under the influence of opiates. The subsequent history of the case was that the pains gradually subsided with loss of power in the leg and permanent paralysis of the anterior tibial group of muscles. Finally, in all epidemics of poliomyelitis, alongside of the true cases which have developed all the symptoms of paralysis, there are the abortive cases, in which there occur all the symptoms of the onset of the disease, but in which there is no paralysis, the patients being ill but a few days and making a complete recovery. In other words, there is some general infection, but no lasting symptoms. Except in the presence of an epidemic, McClanahan says the diagnosis of the abortive type could not be made, without the occurrence of the disease in other children, in the same household. In that case, if the child had all the symptoms, and recovered in a few days, without paralysis, then such a diagnosis would be justified.

123. Poliomyelitis.—From May 30 to July 4, 1909, there occurred in the Stromsburg territory (a place of residence) 30 cases, while from July 4 to August 3, there were 115 cases. The first case that is suspected of being infectious poliomyelitis in Polk County occurred about the middle of May, 1909. The patient was a child 5 or 6 years old who came from some distant part of the state, just after recovering from the acute stage. The first case that Anderson saw occurred 11 miles northwest of Stromsburg on May 30; the patient had been ill for one week and during that time had been under the care of a physician from the nearest town who had made a diagnosis of influenza. Of the 86 patients seen by Anderson, 84 per cent. were less than 10 years old. In 40 families of 150 children, 86, or 57 per cent., contracted the infection. Isolation of the sick was carried out so far as possible, and when many were sick in one family infection had usually occurred before medical aid was called.

The number of patients who recovered from the acute symptoms in less than a week was 32. Thirty of these showed no marked paralysis, except that a leg might suddenly give way while walking along, thus causing the little patient to fall oftener than usual. The spine was more or less spastic, especially in the cervical region and the gait commonly stiff and awkward. The remaining 2 were paralyzed as follows: left leg and right arm, recovery almost complete in 5 months; mental symptoms, recovered in 9 months. Seventeen recovered from acute symptoms at the end of a week; 8 had no well-defined paralyzes, and 9 were paralyzed. Three have not yet fully recovered; facial paralysis, one leg and back; both legs, subsequent history unknown. Seven recovered from the acute symptoms at the end of 2 weeks, one without paralysis and 6 paralyzed. Two recovered from paralysis as follows: one was affected mentally and recovered in one week; one eyelid paralyzed, recovered in 2 months; two paralyzed in one arm and two in one leg and were not completely recovered for 8 months.

Twelve patients recovered from the acute symptoms at the end of 3 weeks, and all were paralyzed. Six recovered from paralysis as follows: one leg recovered in 7 months; right arm recovered in 6 weeks; diffuse weakness, recovered in one week; both legs and back recovered in 2 months; both legs recovered in 5 months. Six patients have not yet (8 months) fully recovered from their paralysis: Right leg two patients; left leg, one; left leg and trunk, one; left leg, one; one arm and one leg, one. Seven patients recovered from the acute symptoms at the end of 4 weeks, and 3 recovered from the paralysis in 3 months: Both legs, 2 cases; one leg, one. Four have not yet (8 months) recovered from the paralysis: right leg; both arms; both legs and trunk. Of the 82 surviving patients, 48, or 60 per cent., were at first markedly paralyzed, and, of

these, 27 have since functionally recovered, while 21 are yet more or less paralyzed, many of whom will need some orthopedic treatment to prevent deformity. Four patients in this series died, all of bulbar paralysis.

The treatment was eliminative and supportive with rest in bed in the lateral position. Cold was applied to the head and counter irritation used along the spine. Hot baths after the fever stage seemed to relieve the intensity of the neuritic pain somewhat. One patient improved remarkably during the night following the fumigation, while inhaling the formaldehyd fumes yet remaining in the bed clothing. The previous day the pain and the muscular contracture of the leg prevented extension of the knee to more than right angle, while the following day it could be extended completely, and even permitted some walking. No especial importance is attached to this, however, as improvements were frequently sudden.

124. Poliomyelitis.—Malter treated 54 cases of epidemic poliomyelitis occurring in 40 families. Four of these patients were adults: Children in families, 96; children that had it, 50; families in which all children had it, 21; families of only one child, 10; paralyzed (30.3 per cent.) 16; recovered from paralysis (66.2-3 per cent.) 11; left paralysis (33.3 per cent. or 10 per cent. of all) 5; deaths 1 per cent.; recurrences 2; paralyzed, able to walk (one not old enough) 3; paralyzed before called (these are the only ones that cannot walk) 2. Ages of patients 9 days to 37 years. Of the 50 children, the oldest two were 10 and 12 years, and the remainder under 10 years. Nearly every case could be traced to some other case or to a locality where the children played together. Quarantine checked it and caused fewer in the family to have the disease; and isolation, together with care in not allowing kissing of the sick, eating and drinking after the sick, etc., also helped to check it.

140. Published in the *American Journal of Medical Sciences*, June, 1910, and abstracted in *THE JOURNAL*, July 2, 1910, p. 83.

141. Peritonitis in Young Infants.—Two cases of peritonitis in young infants are reported by Burdick. The infection in both cases was probably through the umbilicus, although there was no gross lesion in either instance. In one of the cases it is fair to suppose that erysipelas in the mother was the source of the infection, although there were no cutaneous lesions on the body.

142. A Modified Obstetric Forceps.—The particular field in which Kosmak's instrument could be used is limited to that class of cases in which the fetal head is caught at the outlet, where the patient's pains have simply given out and

no further progress of the advancing head is possible. The head may remain in this situation for a considerable time unless it is assisted over the remaining portion of the birth canal by means of forceps. In the instrument described, the hand of the operator comes close to the fetal head which can thus be more readily controlled. As the handles of the instrument are not elevated to the extent which they are in the long-bladed forceps, the points of the blades are not so apt to cut into the perineal floor as the head is being delivered. The Tucker-McLane instrument has been used as the basis of Kosmak's idea. With the exception of being slightly narrower, the size and contour of these blades are the same as in the large forceps, but instead of the usual shank the blades are inserted directly into the handles. The pelvic curve is also slightly less than in the ordinary instrument.

144. **Stomach Contents and Motility of Breast-Fed Infants.**—The stomach was found empty by Heiman at the end of 2 hours in 4 out of 13 cases, and in 5 out of 9 at the end of 3 hours, and in 5 out of 6 at the end of 4 hours. Free hydrochloric acid was present in 2 patients, 7 and 8 months of age, respectively. Pepsin was present in only 6 cases. Rennet was demonstrated in all but 2 cases, lactic acid was present in all but 3 cases. These data differ considerably in many respects from those recorded in previous studies.

- 157 Eclampsia. A. Samuels, Baltimore.

154. **Eugenic Movement.**—This survey of the subject of eugenics is closed by Barker as follows:

Fragmentary as has been this presentation, I trust that it may stimulate thought regarding the eugenic ideal, and hope that the subject will be studied and that the people may become instructed in it. In becoming thorough eugenicists, we shall act in accordance with the highest aims and purposes of all persons interested in true social hygiene. Though the old doctrine of predestination gets new support from the recent studies, these studies also teach us how mankind can control its destiny. It will be absolutely necessary to attack the problems of (1) the improvement of races and families, and (2) the extinction of hereditary disease in the one single way in which permanent betterment is possible. We must more consciously control the union of germ-cell qualities, and we can do this by creating new sentiments regarding marriage and parenthood.

156. **Epileptics in Separate Institutions.**—Shanahan urges that the patients should be divided into the voluntary and the legally or judicially committed. Many of those sent to a colony should be kept there indefinitely, both for their own good and for that of the public. The colony authorities should also have power to secure the commitment of those whose mental condition precludes their being able properly to become resident outside of an institution. The patients committed should, as a rule, be kept in the colony during the remaining years of their life. This might be at first, perhaps, looked on as a hardship, but when they learned that the restrictions laid on them were not unduly severe, they and their relatives would, as a rule, cooperate to the best of their ability. The epileptic who is congenitally defi-

cient to a marked degree or the one who is profoundly demented, will not improve as a result of colony treatment. The average epileptic does, however, show some improvement after a residence of several months, and from 3 to 4 per cent. have a complete cessation of seizures. At the Craig Colony 16 patients have been free from seizures for 2 years or longer, and in 14 years, 46 have been discharged as recovered. Shanahan can see no good reason why, if properly planned, a colony cannot be arranged so as to care for all types and classes of epileptics, thus enabling the other institutions for the abnormal to carry out their work to better advantage.

167. **Defectives and Degenerates.**—Keniston urges that the state law prohibiting the marriage of epileptics and the feeble-minded should be enforced. It should be somebody's business to enforce it. All "imbeciles with criminal instincts" should receive life-long care and supervision. Sterilization of the unfit—vasectomy—is essential, as it benefits the individual as well as the community. Prevention is the most important thing, if it be possible. Every physician should study and record every defective or degenerate he knows to be such.

168. **Animal Serum in the Treatment of Hemorrhage.**—Beach reports 8 cases, 3 in which the serum was used as a prophylactic and in 5 in curative doses, 2 of the latter patients being hemophiliacs.

British Medical Journal, London

July 30

- 1 *The Evolution of the British Medical Association and its Work. H. T. Butlin.
 - 2 *The Dominance of Etiology in Modern Medicine. J. M. Bruce.
 - 3 *Malignant Disease. H. G. Barling.
1. **Evolution of the British Medical Association.**—Butlin limits himself entirely to an historical review of the British Medical Association.

2. **Modern Medicine.**—After a brief review of some of the most important advances which have been made in medical science and practice during the 15 years which have elapsed since the Association last held its meeting in London, Bruce draws attention to the general nature and character of the progress made. This, he points out, has been chiefly characterized by a change in the general tendency and direction of investigation, so that instead of concentrating attention on the lesions produced by disease we have advanced to the elucidation of the processes leading up to those lesions, the causes determining them, and the various influences controlling and modifying the actions of those causes. The recognition of the paramount importance of etiologic considerations and of the closely cognate subject of functional pathology is regarded by Bruce to be deserving of historic recognition as the dominant feature of the medical research of the past 15 years.

After demonstrating the fundamental importance of the doctrine of causation, Bruce proceeds to analyze the nature of causative processes and of their relation to one another. Taking as an example acute infections, he differentiates three factors—first, the essential cause, which is specific in nature and extrinsic in origin; second, the patient's resistance, which is intrinsic; and, third, those various conditions which favor the action of the exciting cause, and are usually classed as incidental, indirect, or predisposing causes. It is more particularly to this third etiologic factor that Bruce devotes the greater part of his address, pointing out the importance of these considerations to the practitioner, not only as most valuable aids to prognosis, treatment and personal hygiene, but also as affording him valuable opportunities to participate in the advance of medical science. The bedside, the home, and the general environment of the patient, he says, offer fields for research as hopeful and as fruitful as the laboratory. It is with a patient, not with a disease, that the experienced practitioner is concerned, with a process, not with a lesion. Such a man appeals to the clinical laboratory when it can assist in the discovery of the exciting cause or in the determination of the organ at fault, but in his actual search for the cause of disease in his patients he has more often to rely on personal observations of the subject, of his surroundings, habits and mode of life, on knowledge of particular family history, and, perhaps, on general knowledge of human nature, the outcome of worldly experience.

3. **Malignant Disease.**—Barling discusses the subject from three premises: (1) What experiment has taught us as to the growth of transplanted carcinoma and the methods by which immunity can be conferred on inoculated animals; (2) our knowledge of resistance to malignant disease in the human subject; (3) the means available for its successful treatment. He says that experiment has told us much of the growth of cancer, and of the means by which inoculated tumors may be inhibited and cured, but it has nothing yet to tell of the origin of cancer. Experimental immunity has so far been obtained within very narrow limits, and the alleged successful treatment of mouse carcinoma by a fluid from the human subject appears to contradict practically all that has been hitherto demonstrated with regard to experimental immunity.

Of the absolute nature of the resistance to malignant disease at present we know little, if anything. We cannot recognize the factor which heightens or lowers it, whether it be a chemical variation in the tissues, or an influence produced through the nervous system, stress or anxiety perhaps exaggerating or exaltation diminishing the activity of the growth. Barling thinks, however, that we can recognize one striking feature in the destruction of the cancerous epithelium which is common to the experimental production of immunity, to the disappearance of growths under radium, to spontaneous recessive processes in the human body. This is the active part played by the connective tissues; we have an irritative overgrowth, with hyperplasia and subsequent contraction, which appears to determine the death of the epithelial cell.

Speaking of the means available for the cure or the amelioration of malignant growths, Barling says that certain modes of treatment by cancer serums, by drugs, and by enzymes may be disregarded as futile. The x-rays have a real field of usefulness in relieving pain, in reducing the activity of inoperable growths, in healing rodent ulcers, if we are justified in including these among malignant formations. When, however, we examine the absolute curative value of this method of treatment, disappointment awaits us. Barling has never known an unequivocal malignant growth absolutely disappear under the influence of the x-ray, though apparently others have occasionally been more fortunate. Radium, he thinks, is curative in rodent ulcer, with this reservation, that the permanence of cure must be certified by a longer period of time than has yet elapsed in most of the cases treated. His main objection to the use of radium even tentatively in such cases is the constant danger of lymphatic and vascular dissemination which may occur in the period occupied by treatment. For the present he would limit radium to the treatment of the least hopeful conditions until much wider experience has been obtained.

As to the treatment advocated by W. B. Coley, especially for sarcoma, the use of the mixed toxins in Great Britain has not given such results as those attained by the originator of the treatment. In the majority of Barling's patients no improvement has been effected, but in others he can speak of improvement which promises cure if further lapse of time confirms the results at present attained. With such experience as he has made, Barling would not advise any patient with an operable sarcoma to adopt Coley's treatment, and he would dissuade him from it as a substitute for operation, but if operation were refused, or the growth were inoperable, he would advise the use of toxins, with the expectation that some patients would be greatly benefited. With every desire to use all means available which may relieve patients of the distress, anxiety, and possible mutilation which operation inflicts, with the belief that time will provide happier and gentler means than we now possess, Barling says that at the moment we have to rely on operative measures as the great remedy for malignant disease. If all malignant growths could be excised at a certain stage in their development all these patients could be cured.

7. **Pathology of Prostatic Enlargement.**—It is held by Paul that the accepted theories as to the cause of prostatic hypertrophy all fail because each can only apply to a limited number of cases. The prostate and the breast are both controlled by their respective dominant sexual glands and respond to their influence in a similar way in health and disease. Both organs are subject to a disturbing influence at the climacteric period, which may, and frequently does, result in a hypertrophic change. In such change the microscopic appearances in the two organs show a remarkable resemblance in all essential details. Prostatic hypertrophy, like the mammary involution hypertrophy, occurs only at the climacteric period, whereas there is no known neoplasm which is so strictly limited to an age-period. For these reasons, Paul considers that prostatic hypertrophy is not due to a chronic inflammation of

septic or specific type nor to a neoplasm, but that it is an involution change similar in character to that occurring in the mammary gland.

8. Helminthic Infection.—The work on which this study is founded was undertaken to ascertain whether the *Clonorchis sinensis* (syn. *Opisthorchis sinensis*, is or is not responsible for any degree of eosinophilia. In only 2.1 per cent. out of 512 patients examined did the feces fail to show the ova of one parasite or another. *Ascaris lumbricoides* was found in 76 per cent. of the cases, and was equally prevalent among students, merchants and farmers. *Trichocephalus trichiuris* was found in 72.6 per cent. All classes were equally infected by it. *Ankylostoma duodenale* and *Uncinaria americana*—one or other of these parasites was found in 60.4 per cent.; both were often present in the same individual. *Clonorchis sinensis* was found in 16 per cent. out of 267 patients examined at Chao-chow-fu, but in only 2 out of 295 patients in the hospital at Suabue. Both of these cases were imported from the Chao-chow region. The natives of both regions have the same dietetic and other habits. Whyte claims that the more varieties of parasite that infest a man, and the more numerous the individuals of each variety, the greater degree of eosinophilia he is likely to show. This will be especially marked if he is between 20 and 40 years of age, and will be less noticeable if he is older or is suffering from some form of tuberculosis.

10. Successful Treatment by Colon Lavation.—The benefit derived from lavage of the colon in certain cases of cutaneous eruptions suggested to Mantle that the skin disturbance should be more frequently associated with toxic absorption from the bowel than from the stomach, though doubtless the two absorptions are frequently associated. Mantle claims frequently to have found, after some experimental douches in cases of eczema, usually with, but at other times without, constipation, a considerable amount of mucus, and treatment directed to this abnormality has resulted in the cure of the skin manifestation. He has, therefore, been led to connect the abnormal condition of the colon with the eczematous condition of the skin, and to consider the latter as due to a toxemia of intestinal origin. When there is no skin eruption following a definite type with this condition of colon, there is usually a muddy appearance of the skin noticeable, and sometimes, in addition to this, an eczematous or other eruption. In several cases of psoriasis when the symptoms and experimental douching have pointed directly to an intestinal causation, the treatment already described has been brilliant in its results. In other cases with no particularly well-marked colitis good results have often, though not invariably, attended washing out the colon. A number of cases of acne vulgaris and of acne rosacea, the latter being in association with acne vulgaris, have been treated on these lines. Intestinal lavation has been prescribed with success, but as in practically all these cases there is found a lack of proper attention to the scalp, this as well as the face must receive special attention.

With pruritus ani there is not infrequently a certain amount of eczema around the anus, and the rectal mucosa is often involved in the itching. In all cases in which eczema has existed, Mantle has found it to be the external and visible sign of a catarrhal condition of the mucous membrane of the colon, and internal douches of alkaline sulphur water, followed by immersion baths of the same water, have brought about such a marked change in the condition of the colon that the local skin lesions have soon cleared up.

The method adopted in carrying out this special treatment by lavage for mucous colitis, associated or not with skin eruptions, is as follows: An alkaline sulphur water is generally used both for the intestinal douche and for the immersion bath which follows it. The object of the internal douche is to wash away old fecal matter and mucus from the colon, and to give the mucous membrane an antiseptic dressing. This is done in the following way: A long rubber tube, after being sterilized by boiling, is passed into the sigmoid and is attached to a hydrostatic douche, when from 20 to 40 ounces of sulphur water at a temperature of 105 F. pass into the colon at a pressure of two feet, the patient lying first on the

right side, then on the back, and lastly on the left side during the operation. This is repeated, and the ejecta after each douche are carefully examined. A warm immersion bath of sulphur water follows the internal douche and when in this bath a hot douche at a higher temperature plays on the wall of the abdomen under water from a large nozzle with fine perforations, and is chiefly directed over the site of the colon.

14. Method of Staining Deep Colonies.—The plates are made in Petri dishes in the usual manner. Ordinary agar can be used; the method is equally successful with modifications of agar, such as glucose, glycerin and whey agar. With a sterile scalpel cut a square of the desired size around the colony and lift out the slab of agar by inserting a wet chisel under it. Push the slab on to the slide, taking care to include no air bubbles; allow to dry in 37 C. incubator or other hot place, and soak in methylated alcohol for 20 minutes. Next put in 5 per cent. solution of the acetic acid for about 10 minutes to dissolve surface crystals. Wash and dry in incubator until the agar is quite dry, which usually takes about 20 minutes. Pour on scarlet writing fluid and allow to remain on until the deep colonies are well stained. This usually takes from 10 to 20 minutes, according to the thickness of the agar. Pour off and blot the edges and press lightly with soft paper to express any ink that may run under the edges of the slab. Now pour on Loeffler's methylene blue, diluted with an equal volume of distilled water, and tilt the slide well until the ink is discharged from the agar and it turns violet. Decolorize in spirit until the color ceases to come out in a visible cloud; finish dehydration in aniline oil, pass into xylol, and mount in Canada balsam. It will be found that the organisms are stained a deep purple, and the agar medium a very pale green.

21. Bacterial Content of Ice Cream.—The 28 specimens of ice creams and ices examined by Bradley in the majority of cases disclosed gross contamination with organisms of fecal origin and cocci of the pus-forming type, not with simple air-borne organisms, indicating that the contamination is most likely: (1) from milk used; (2) from dirty receptacles; (3) from handling. In 6 quantitative examinations the organisms growing in 12 hours at 37 C. exceeded 30 millions per c.c. in 3 cases. In one case there were over 17 millions, in another 500,000, and in a third the ice was possibly sterile, not 20,000 per c.c. The colon bacilli were present in the typical fecal types, and the numerical distribution of these types was such as one would find in feces.

27. Rectal Serotherapy in Gonorrhea.—This case responded remarkably to rectal serotherapy, after failure with all other usual remedies. Treatment was unsatisfactory as the patient was off and on alcoholic. He had various mixtures and injections, with no improvement; the discharge continued to be profuse, and he got into a miserable state, with incontinence of urine and strangury. Six months after the initial infection Salter began a course of vaccine treatment, the prostatic symptoms cleared up. During the course of this treatment the patient got relief from incontinence, but the discharge was apparently uninfluenced, and remained profuse and purulent. Then Salter injected rectally 10 c.c. polyvalent anti-

streptococcus serum, repeating the dose on the two succeeding days. This was followed by immediate and marked improvement; the discharge ceased entirely for two weeks, but as a slight purulent discharge then reappeared, Salter repeated the rectal injections thrice. After this the purulent discharge cleared up, a little mucus discharge only remaining in the morning.

- 37 Leukemia. E. W. J. Ireland.

29. Treatment of Fractures Implicating Joints.—The following precepts are made by Russell:

1. In fracture involving, or in the immediate vicinity of a joint, where there is no gross displacement of the articular surfaces, stiffness of the joint never supervenes, except as the result of passive motion carried out by the surgeon.
2. In fractures involving joints in which there is some displacement or irregularity of the joint surfaces, and in which, therefore, some impairment is inevitable, such stiffness will be greatly aggravated by the employment of passive movement; and complete abstention from passive movement by the surgeon will yield the best results attainable.
3. When great stiffness is present, in spite of the surgeon's efforts to increase the mobility by passive movement, such stiffness will persist so long as the surgeon persists.
4. When the surgeon abandons the case in despair, improvement will at once commence.

Condensing these four laws into one weighty generalization, he says that in fractures involving joints the most potent cause of stiffness is the so-called passive movement performed by the surgeon. Immobilization is never a cause of stiffness. The maximum degree of permanent usefulness is to be obtained by immobilization alone.

30. Simple Fractures.—Buchanan agrees with Russell that in cases of fracture involving joints there are a fairly large number in which early passive movement is not remedial. The methods of Lane and Lucas-Championnière he regards as impracticable, because usually there is no necessity for that of the former nor for that of the latter because its use seems to be fraught with the gravest danger, especially if the movements carried out are not of the mildest character, and directly under the supervision of a skilled person. During the past five years Buchanan cannot recall a single case of marked deformity, ununited fracture or impaired use of the limb in such cases treated by the more ordinary method of manipulation, careful coaptation, assisted by the use of radioscapy, fixation by splints of muscles and joints of the affected limb.

38. Gangrenous Perforation of the Uterus after Abortion.—The case reported by Fieux shows that a gangrenous process may develop in the aborting uterus solely from partial retention of the placenta and putrefaction of the adherent mass. The gangrene may progress to an eschar entailing perforation as it drops off, and all this may occur without any direct traumatism of the uterine wall. Varnier has reported a similar case. In both the abortion had been induced by an intrauterine injection, the nozzle of the syringe not being long enough to reach into the uterus.

39. Hemorrhagic Extrauterine Pregnancy.—In the first case fecundation dated from only a few days and the tube was permeable, without rupture, the hemorrhage pouring into the peritoneum. The blood oozed for more than two days until the tube was removed. In the second case the ovum settled in a diverticulum in the already inflamed tube.

40. Tetany in the Puerperium.—Wallich's patient developed tetany the seventh day after delivery, on receiving news of

the illness of her child. Pinard has encountered but one similar case in his long practice. Wallich inquires whether others have met with cases of this kind, remarking that it is necessary to restrict so far as possible the disturbances laid to the score of the puerperal condition, as physicians should never lose an occasion to demonstrate that pregnancy, childbirth and lactation are physiologic states for the normal woman and not pathologic.

41. Superheated Air in Treatment of Gangrenous Wounds.—The wounds to which Dupont refers are the obstetrical tears which suppurate and show little tendency to heal. He has obtained excellent results by application of superheated air; the hot douche penetrates into all the infected crevices and destroys the putrefying tissues while inducing a reparative hyperemia in the surrounding tissues. In one of the three cases reported in detail this aërothermotherapy rapidly arrested the gangrenous process in the cervix and the development of the threatening vesicovaginal fistula was checked.

- 59 Lateral Suture of the Portal Vein. P. Hallopeau.

54. Oblique Osteotomy through the Trochanter for Vicious Ankylosis.—Quénu and Mathieu give an illustrated description of 3 patients whose deforming ankylosis of the hip-joint was corrected by sawing the femur from the top of the trochanter oblique to a point low down on the other side. The extreme slant permits the neck part to be slipped up on the shaft, thus lengthening the limb while it leaves the largest possible areas of the stumps in contact after correcting the position of the shaft. For correction of a shortening of 8 cm. the line

of section should be at least 10 cm. long which leaves 2 cm. of the cut surfaces still in close contact, not merely the points alone. The slanting section causes the parts to be pressed together along the entire length of the cut surfaces in contact, the contact being aided by traction from the muscles. The osteotomy must be followed by continuous extension, they state, until the parts have healed. By flexion of the trunk on the thigh, rotation of the femur on the pelvis, after the consolidation has reached a certain point, it is possible to obtain some loosening of the ankylosis, aiding materially in the patient's ability to get about later.

55. Umbilical Gall-Stone Fistula.—In the case reported by Patel and Cotte the fistula developed from a gall-stone forcing its way out through the skin from the inflamed gall-bladder. The patient was a woman of 37 who had borne three children and had had gall-stone colic at times during the last 11 years. She was cured of all disturbances by an operation similar to that for obliteration of an artificial anus.

57. Special Type of Pseudocoxalgia.—In over 500 cases of coxalgia, Calvé has encountered 10 in which a brief subacute arthritis healed without impairment of movement, but a pre-existing deformity of the bone persisted unmodified. The children had coxa vara or hypertrophy, atrophy or deformity of the head of the femur, but there was no destruction of bone tissue at any point. The type does not correspond to any of the known forms of hip-joint disease, and it has generally been mistakenly diagnosed as a tuberculous coxitis. The children begin to be occasionally a little lame and complain of pain in the knee, the movements of the joint are limited and there is some muscular atrophy in the region. After a certain period the pain subsides, with or without extension in the interim, and the children walk normally or with a slight limp. The features of the cases differ entirely from those of dry caries of the hip-joint and deforming juvenile osteoarthritis. In his first cases differentiation was retrospective by examining more attentively the radiographs which had been taken as the children first came under treatment for supposed tuberculous hip-joint disease.

60 *Hemorrhages in the Non-Pregnant Fallopian Tube. (La pachysalpingite hémorragique.) L. Bazy.

60. Hemorrhages in the Non-Gravid Tube.—Bazy's profusely illustrated article is based on 2 cases and on 2 other less typical examples of what he thinks may be described as a hemorrhagic pachysalpingitis. In a fifth case a tubal pregnancy was accompanied by this form of inflammation in the other tube. The rupture of the gravid tube put an end to the pains on this side while the pains in the pachysalpingitic tube persisted unmodified. Differentiation of this hemorrhagic inflammation is practically impossible, he says, before operating.

Revue de Médecine, Paris

July, XXX, No. 7, pp. 529-612

61 *Clinical Study of the Rhythm of the Secretion of Urine and of Diuresis Induced by Ingestion of Water. H. Vaquet and J. Cottet.

62 *Incomplete Form of Pericholecystitis of Gall-stone Origin. P. Londe.

63 Influence of Intoxication from a Substance Inducing Anaphylaxis on Nitrogen Metabolism. P. Lassablère.

64 Action of Vichy Thermal Waters on Arterial Tension. A. Therre.

61. Clinical Study of the Rhythm of the Secretion of Urine and of Diuresis Induced by Ingestion of Water.—Vaquet and Cottet emphasize the importance of not drinking more fluid than the kidney is able to eliminate; in heart and kidney disease the amount should thus be reduced to conform to the eliminating power of the kidneys. This they test by the experimental polyuria test, that is, the diuresis that follows ingestion of over a pint of water, fasting, the patient reclining for nearly two hours afterward. Recumbency materially promotes the diuresis, and they advise having the patients lie down for a couple of hours after the morning draught in all courses of mineral waters. Obese patients lose weight more rapidly with this recumbency to promote diuresis than when they keep up after drinking the water. The rhythm

of secretion of urine is tested by keeping separate the urine voided between 9 p. m. and 7 a. m.; 9 a. m. and 9 p. m. and between 7 a. m. and 9 a. m.; the latter period is that of the experimental polyuria after ingestion of 600 c.c. of mineral water (Evian).

62. Pericholecystitis.—Londe gives the details of 15 cases out of a total of 30 or 40 of a syndrome including a tendency to vomiting, vague abdominal pain and dyspepsia and more or less tenderness in the gall-bladder or stomach region or below. The pain sometimes is referred to the right shoulder as the abdomen is palpated. The main danger from the pericholecystitis is infection of the peritoneum, and operative treatment is justified with a history of some preceding severe attack, or the lingering nature of an apparently mild syndrome. Beware, Londe says, of the cases in which the patient eats and feels well but gradually tends toward cachexia—any discordance between the subjective and objective signs is instructive. The prognosis is less favorable if mild chologogues and alkalines are not borne well, as in chronic appendicitis. Some of the cases reported in detail show the danger of delay in operating when the recurring attacks grow more severe. In one such case, subhepatic peritonitis developed and the patient succumbed to thrombosis. In one case the subfebrile pericholecystitis seemed to flare up anew before the menses each time.

Semaine Médicale, Paris

July 7, XXX, No. 80, pp. 319-360

65 *Hypnotism in Therapeutics and from Medicolegal Standpoint. J. Babinski.

65. Hypnotism from the Therapeutic and Medicolegal Standpoints.—Babinski is inclined to regard hysteria as about half simulation, and hypnotism the same. For example, he says, if a hypnotized individual has suggested to him that the house and stairway are on fire, he may exhibit terror but he will never be so terrified as to jump out of the window. Numbers of hysterical individuals have been cured after they have been hypnotized, he remarks, but psychotherapy waking would have been equally effectual in all, unless the hysterical patients had clamored for the hypnosis. From the medicolegal standpoint he insists that hypnosis does not deprive the subject of will-power to the point of committing a crime which he would not commit under other circumstances. The hypnotized individual is responsible for criminal deeds which he may commit, and even slight attenuation of the responsibility can be admitted only when the individual has been in the habit of being hypnotized frequently so that a special hypersensitiveness may have developed.

66. Lessons from Ten Years of Abdominal Operations.—Thiemann reviews the experiences at the surgical clinic at Jena in charge of Riedel, and emphasizes the following points:

Swallowed foreign bodies very rarely cause ileus. If the foreign body has passed through the esophagus it generally slides along through the bowel without he great danger in the descending part of the duodenum. Perforation by a foreign body is a peculiar tough induration of the vicinity, which may secondarily interfere with the permeability of the bowel.

Cancer of the duodenum causes comparatively slight local symptoms in comparison with the general cachexia. The favorable influence of a simple laparotomy on tuberculous peritonitis is confirmed by the experiences related. The success of operations for correcting atresia of the rectum is often compromised by malformations elsewhere.

In 36 of the 321 cases of incarcerated hernia the trouble was an acute partial enterocoele; the disturbances are so slight while there is so much danger of perforation even with cautious reduction that the mortality is unusually high, 41 per cent. It occurs almost exclusively with femoral hernia, but 3 out of the 4 cases of obturator hernia were partial enterocoeles.

The symptoms with torsion of the appendices epiploicae were extraordinarily severe.

The best measures to sustain the patient after operations are rectal saline infusion and systematic lavage of stomach and bowel. Physostigmin generally fails, and saline-suprarenal extract infusion has only transient effect in peritonitis.

Perforation of a typhoid ulcer is inevitably fatal unless the process becomes walled off by adhesions.

In little girls, the peritonitis set up by diplococci, staphylococci or streptococci has a grave prognosis, contrary to that of gonococcus peritonitis. In 13 cases of this kind, only 2 of the patients were saved. In one case a right crucial incision showed the whole abdomen full of pus, the appendix being apparently normal and the tubes inflamed. After wiping out the abdomen it was completely sutured and the girl, aged 13, recovered after a few days of fever. Infection is by way of the genital tract and it may occur without lesions in the latter.

Symptoms suggesting flueus may develop after pneumonia, pleurisy and pericarditis, but the abdominal findings are negative. An important differential sign in such cases is the good aspect of the tongue.

Chloroform general anesthesia does not seem to affect the course of pneumonia unfavorably.

With acute dilatation of the stomach resisting all other measures, gastroenterostomy is justified.

Postoperative paralysis and dilatation are most effectively combated by early systematic lavage of the stomach.

Saline rectal infusion seems to be the most effectual means to prevent postoperative adhesions but the adhesions developed by the suppurative process are not influenced by it.

All stumps should be covered with peritoneum, and before removing a high rectal cancer, the peritoneum should be shut off above through a left crucial incision.

68. Indications for and Mode of Action of Gastroenterostomy.—A similar article giving Rovsing's views and experience was summarized in *THE JOURNAL*, Jan 15, 1910, page 248.

69. Plastic Operations on the Face.—Lexer's article is accompanied by 35 illustrations showing his technic and the results in various cosmetic operations, formation of a nose or ear, correction of hare-lip or defects left from removal of cancers in the face; in some cases he transplanted part of the scalp to supply a moustache or beard, in others a wedge from the tibia to make a frame for the nose. In some cases he supplied the lacking support for the skin by inserting a flap of adipose tissue from the abdominal wall. The favorable results of this free fat transplantation and of similar experiments on animals promise a future for this method. In the first case it was applied to remedy a deep depression in the cheek and temple left from suppuration after traumatic injury; in the other case to remedy ankylosis and atrophy of the jaws, introducing the round flap of fat through an opening under the chin. This method has been applied since to correct defects in the breast after excision of a benign tumor and for defects in the cheek.

70. Cancer Metastasis in Ovaries and Pouch of Douglas.—Rosenstirn reports 15 cases which emphasize the importance of the attraction of gravity in determining the location of metastatic growths from abdominal cancers. The primary cancer may be still securely enclosed in serosa and yet metastasis by implantation may occur from it. The laws of gravity, he declares, explain why the ovaries are so often involved. Still more often the implantation occurs in the very lowest part of the pouch of Douglas, and it is important to examine this region in all operations for abdominal cancer.

74. Prophylactic Plastic Operation for Acute Ulcerative Intestinal Lesions.—Solieri reports a case of paratyphoid intestinal ulceration in which he wrapped the bowel, just as it was on the point of perforation, in part of the omentum, fastening the omentum to the mesentery just below its attachment to the loop in question. The laparotomy did not affect the patient unfavorably, while the protecting sheath of omentum thus provided for the bowel warded off perforation and peritonitis. He calls the operation "omental enterocoeleisis" (from *kleio*, I surround), and remarks that it is scarcely more serious than an exploratory laparotomy.

77. Abnormal Development of the Pelvis.—Hegar remarks that much can be done in prophylaxis and correction by breast nursing, improving the hygienic conditions of the poor, and physical training of the young. Nature strives to correct disturbances in development by tardy growth late in life. This is observed especially in women under the influence of married life and pregnancy. The uterus and breasts may grow out of an infantile condition late in life; likewise the pelvis at an age when its growth might be considered as definitely arrested, may continue to develop, especially under the influence of pregnancy. This may explain Sellheim's observation that the proportion of women with infantile pelvis grows constantly smaller after the age of 25 to 30.

79. Hypoplasia and Infantilism in Relation to Gynecology and Obstetrics.—Mayer discusses the various manifestations of hypoplasia and infantilism in the genitalia and the clinical importance of these anomalies, especially the light which they throw on physical processes. His article is based on the experiences at the Hegar, von Rosthorn and Sellheim clinics for women's diseases, and is profusely illustrated. Individuals of this type, he says, must be regarded as "unfinished," and the resulting disturbances have special importance from the standpoint of social insurance against invalidity.

89. Treatment of Hysterical Loss of the Voice.—Senator relates that his experiences with Seifert's method of treating hysterical aphonia have not been so favorable as those reported by Seifer, but still he found it successful in a number of cases in which no benefit had been obtained from other measures. The patient's head is bent far over backward or the entire upper part of the body is tilted back. In this position the patients find that they are able to speak or intone. Seifert found that he was unable to speak in a whispering tone when his head was bent over backward in this way. The upper part of the body must be completely relaxed. In the two cases refractory to this measure in Senator's experience, the aphonia was promptly cured by other measures in the first, and in the other a thickening from chronic laryngitis may have been responsible for the failure. He is inclined to explain the success of the measure in general as due to its moral influence, adding another weapon to the armamentarium at our disposal for effectually influencing hysterical aphonia. The list includes manual pressure on the larynx, electric vibration massage, improvement of the respiration, a deep breath being taken before each single sound, and training the patients to speak in a lower key, the hysterical-aphonic patients generally having had a high-keyed voice.

94 *Present Status of Cancer Research. (Ueber den gegenwärtigen Stand der Krebsforschung.) M. O. Wyss. Commenced in No. 20.

92. **Bronze Diabetes.**—Bernoulli gives the clinical and autopsy details of a case of bronze diabetes with intense glycosuria in a man of 38 inclined to hemostasis and headache, with pneumonia three years before. He states that he has found 41 detailed reports of cases of so-called bronze diabetes in the literature, and that in 7 there was no tendency to glycosuria.

93. **Epidemic Poliomyelitis.**—Eichhorst encountered 3 cases last year at Zurich although no epidemic of this disease has ever been known in Switzerland. He mentions that during the last four years an unprecedented number of cases of epidemic cerebrospinal meningitis have been observed at Zurich, from 8 to 23 cases each year at the clinic in his charge. He remarks that epidemic poliomyelitis interests in nearly equal degree the bacteriologists, epidemiologists, internists, neurologists and pediatricists, surgeons and orthopedists, and he applies the great general's appeal to his soldiers: "In scientific things press on alone, if necessary, but in attacking epidemics strike all together."

94. **Cancer Research.**—Wyss concludes his review of the present status of cancer research with the statement that the main thing now is to collect extensive and uniform statistics for comparison. He thinks that cancers should be classed not according to the tissues in which they are formed but according to their localization and origin. For this he proposes four classes:

1. **Involution carcinomas:** This includes cancer of the uterus, ovaries and breast, that is, organs of reproduction which regularly retrogress, aging according to certain early time limitations.

2. **Intestinal carcinomas:** This includes carcinomas of the alimentary canal, the organs which are most affected by the mode of life, the food and habits, and which are most subject to repeated mild infections.

3. **Irritation carcinomas:** This includes the cancers developing from repeated mechanical irritations, especially those of the tongue, lips and skin, larynx and biliary passages.

4. **Carcinomas of all other origin or which cannot be grouped with the above,** as those in thyroid, pancreas and lungs.

To illustrate the advantages of this classification, he gives a chart showing the prevalence of these various groups in several Swiss provinces during the last eighteen years. The chart shows that the involution cancers are most frequent in the provinces containing the larger cities, while the intestinal cancers and especially gastric cancer are responsible for the larger numbers of cancers in the provinces where cancer is most prevalent, Schwyz and Lucerne.

103 Moving Roentgen-Ray Pictures of Internal Organs. (Ueber Röntgenkinematographie—Bioröntgenographie innerer Organe des Menschen.) A. Wertheimer.

95. **Cardiovascular Neuroses.**—After reviewing the differential points Rumpf discusses treatment, emphasizing the necessity for discontinuing tobacco—he has several times, he says, witnessed an acute toxic action on the pulse from a single strong cigar. He also refers to helminths as liable to induce an acute cardiovascular syndrome. Repose is an important factor in treatment, especially an out-of-door rest cure when combined with systematic deep breathing to exercise the diaphragm. He tells the patient to place his hands lightly on the stomach and breathe so that during inspiration the abdomen bulges in front and downward. This relieves the

heart materially as the compression of the abdominal contents forces blood and lymph into the thorax, and, as the diaphragm rises, the blood is further forced along in the chest veins. As the pericardium is adherent to the diaphragm, it is drawn down with the latter, stretching the heart lengthwise, and counteracting the widening influence of ordinary breathing. Long-continued, moderately deep, abdominal breathing sometimes permanently retarded the heart rate. The unusually rapid heart action in certain bicyclists may be traced to the lack of abdominal breathing. When the patient has been trained to abdominal breathing, gymnastic exercises can be cautiously commenced but the bending forward or twisting of the trunk must occur during an inspiration, and expiration accompany the raising of the trunk erect. Done in this way the exercises do not accelerate the pulse. All the exercises must be done with abdominal breathing. Massage and rhythmic compression of the abdomen and of the lower thorax are also useful to promote the circulation in the abdomen and with threatening collapse and edema of the lungs. Persons of sedentary habits are liable to do irreparable harm to their heart by over-exercise on vacations; especially the elderly should be warned against rowing, fencing and mountain climbing. The family physician should emphasize the necessity of prophylactic moderate physical exercise which is too often crowded out of the modern strenuous life. Rumpf warns against prescribing spa treatment for functional disturbances, as association with individuals with organic disease is liable to have an unfavorable influence. Mild hydrotherapy can be applied at home; the best measures are those which divert attention from the heart. The suggestive influence of the physician is of paramount importance in those cases in which a mild organic affection is accompanied by severe functional disturbances. A wise wife, Rumpf adds, can protect her husband in these cases against many annoyances and excitements, but what a world of superfluous annoyances a fool of a wife can load on her husband! The choice of reading matter is another element that may favor or hinder a cure.

96. **Experimental Treatment of Cancer.**—Reicher states that the active principle of the suprarenals injected around an experimental tumor on mice almost invariably led to its subsidence. From 5 to 13 injections accomplished this in rats and the results observed, he declares, encourage a trial in suitable clinical cases.

97. **Myogenous Leukocytosis.**—Grawitz examined the capillary blood and the blood from the ulnar vein before and after muscular effort and found in both a marked leukocytosis following the exertion. The leukocytes jumped from 4,400 to 11,200 or 7,500 to 11,700 in a few minutes. The increase cannot, he says, be ascribed to different distribution of the corpuscles. There is pronounced lymphocytosis at first but neutrophile leukocytes soon predominate.

98. **Habitual Use of Chloroform.**—A woman of 51 inhaled from 40 to 60 gm. of alcoholized chloroform (equal parts) almost daily for 15 years, but no signs of a cumulative action were apparent and there were no symptoms on suspension of the chloroform. She acquired the habit from a medical prescription of the preparation to apply locally to the face to relieve severe migraine.

101. **Improved Technic for Forensic Examination of Old Spots of Seminal Fluid.**—Gasis loosens up the spermatozoa with a 1 to 1,000 solution of corrosive sublimate, then stains with 1 per cent. solution of eosin and decolors with a 1 per cent. solution of potassium iodid.

108 *Symmetrical Gangrene in an Infant. (Raynaudsche Krankheit beim Säugling.) C. Beck.

104. **Lime Salts, Phosphorus and Cod Liver Oil in Rachitis.**—Schabad writes from the pediatric clinic and laboratory of the Peter-Paul hospital at St. Petersburg to reiterate his former statements in regard to the efficacy of a combination of phosphorus and cod-liver oil in rachitis, and that calcium acetate has a remarkable effect in favoring retention of lime in connection with the phosphorus and cod liver oil. None of the other lime salts he tested seems to have this property, he states, the phosphate and citrate being all eliminated. His work is based on minute research on the metabolism and he tabulates the findings in one of the typical cases examined over a long period.

103. **Symmetrical Gangrene in an Infant.**—In the case reported by Beck, the first child of healthy parents was apparently healthy until nearly five months old, when the mother noticed recurring capillary congestion and bluish discoloration of the hands, feet and ears. In the course of six weeks the cyanosis recurred every day, gradually becoming almost continuous and gangrene developed. The child died in a month with signs of heart weakness and serious atrophy and beginning gangrene of the left hand. The only pathologic findings at autopsy were patches of thickening of the intima of all the arteries of the extremities and in some of the veins on the arms, while the brain and spinal cord were apparently normal.

109. Progress of Abdominal Surgery.—Moszkowicz concludes his review of the present status of abdominal surgery by appealing to general practitioners to diagnose high rectal cancers earlier. If in every case of rectal hemorrhage of obscure cause and negative findings with digital examination, the region was examined with the proctoscope it might be possible to detect high rectal cancers in an earlier stage. At present they are mostly in an inoperable phase when the surgeon first sees them. He urges the practitioner to call in a surgeon to aid in the diagnosis in every case of an obscure gastric or intestinal affection.

110. Idiosyncrasy to Cow's Milk in Infants.—Zybell has found on record 23 cases of an actual idiosyncrasy to cow's milk and adds 3 cases to the list from his personal experience. In one of Finkelstein's cases the resulting disturbances proved fatal, but in all the others the symptoms subsided on suspension of the cow's milk and feeding with small amounts of breast milk generally drawn and given to the infants with a spoon. The idiosyncrasy became manifest as the child, who had been fed at one time with cow's milk and then had been breast fed, was given cow's milk anew. In 5 cases, however, the idiosyncrasy was manifested at the first trial of cow's milk. This fact Zybell regards as sustaining the assumption that the idiosyncrasy is the result of some constitutional anomaly. This assumption is sustained further by the fact that several members of the same family or different generations may display the tendency. Even an hour or two after taking the cow's milk the temperature may run up to 104 F. and over; it may subside again as rapidly as it rose or it may persist for days at this height. In Finkelstein's fatal case the fever kept up for 9 days terminating at 106 F. Along with the fever the child looks collapsed, the skin is pale and cool or eva-

notice, the respiration shallow and rapid, the whole impression being that the child is very ill. This extreme collapse suggests intoxication, but as a rule the threatening symptoms subside after a few hours. Gastrointestinal disturbances were noted in nearly every case and in 2 cases an eruption occurred during or directly after the milk feeding. The infants ranged from 9 to 42 weeks old. In weaning, only minute doses of cow's milk should be given at first to avoid being surprised by the discovery of an unsuspected idiosyncrasy to cow's milk, the manifestations of which may put the child's very life in jeopardy. The idiosyncrasy was finally conquered in all but one case by cautious administration of very small amounts of milk, the exception being a girl, now 15, who is still unable to take even the smallest amount of milk. In all the other cases the idiosyncrasy seemed to disappear as abruptly as it had developed, so that a few days later the children were taking rapidly increasing amounts of milk without the least inconvenience.

113. Treatment of Hemoptysis.—Blümel concludes his discussion of treatment of hemoptysis with the statement that salt is the most reliable means at our command for controlling hemoptysis. It overthrows the existing osmotic balance and fluids then pour from the tissues into the excessively salty blood, bringing with them the thrombokinase, the substance which promotes coagulation in the blood. It has been found that 10 minutes after ingestion of 10 gm. of salt by the mouth the coagulation time was reduced from $3\frac{3}{4}$ to $1\frac{1}{2}$ minutes and to 1 minute after another 10 minutes. This hemostyptic action of sodium chlorid has been utilized by von den Velden in several hundred cases of inaccessible hemorrhage, hemoptysis, gastro-intestinal hemorrhage, etc., and the results were invariably equally good, as also in Blümel's and Reiche's experience. Blümel advises the physician called to a case of hemoptysis to insist on physical and psychic repose, the patient reclining in bed with the shoulders raised to promote expectoration. He must not be allowed to speak or to make any hasty movement and must remain in bed for several days after the sputum has ceased to show traces of blood. If the calm soothing words of the physician are not sufficient to tranquilize the patient, an ice bag should be applied to the heart or 30 grains of sodium or potassium bromid should be given. The ice bag helps to keep the patient still, if it does no other good, but it is not needed, of course, in every case. The application of adhesive plaster to immobilize the lung generally wearies and excites the patient unnecessarily. To check the cough if there is not much expectoration he gives about 3 grains of Dover's powder, if the patient is unable to control the cough himself, or some other sedative, repeating the dose at night, but never giving a sedative early in the morning as expectoration should be favored at this time. The temperature must be taken six times a day and the sputum collected to show to the physician. The food need not be changed if gas-generating and very cold substances are avoided. The room must be kept moderately cool and frequently aired. If the hemorrhage still persists when the physician arrives, he should give at once a heaping teaspoonful of salt in half a glass of water, and if the hemorrhage recurs or threatens, repeat the dose, alternating it with 45 grains of sodium or potassium bromid at intervals of $1\frac{1}{2}$ or 3 hours, as required. If the hemorrhage is very profuse, the limbs may be ligated as an adjuvant—handkerchiefs answer the purpose but the constriction must not be too tight; the aim is to permit the arterial blood to flow into the limb. The greatest care must be exercised in undoing the ligature. If conditions are particularly threatening he advises an intravenous injection of 5 c.c. (81 minims) of a sterile 10 per cent. salt solution. A single dose of horse serum may be used also in these circumstances but it should not be repeated. The coagulating power of the blood may also be promoted, he adds, by a single subcutaneous injection of a sterile 10 per cent. solution of gelatin, repeated as needed. Ingestion of 5 gm. calcium lactate in 50 c.c. water, this dose repeated in 5 or 6 hours, may also be advised. If the patient is suffocating from clots in the throat they should be removed, artificial respiration applied or an emetic administered. Saline

infusion is contraindicated so long as the hemorrhage continues. The physician must never forget that the hemoptysis is merely a symptom and the cause must be sought. Blümel also adds a word of warning against the use of scopolamin and morphin as they have a paralyzing action on the reflexes so that suffocation is liable to ensue, to say nothing of the aspiration pneumonia that may follow.

118. Roentgen Ray Treatment of Uterine Hemorrhage and Myoma.—Krönig and Gauss report 505 cases with operative treatment and 63 with treatment by the Roentgen rays and state that increasing experience is convincing them of the value of the latter in these gynecologic cases. Radiotherapy is definitely restricting the indications for operative treatment with myoma and hemorrhagic uterine trouble. It is especially indicated in cases of much debility, degeneration of the heart, obesity or bronchial catarrh. Operative treatment has still a mortality of from 4 to 6 per cent., which is altogether too high in the absence of vital indications. Excluding the above class of cases, radical treatment would have only 1 or 2 per cent. mortality, and this deserves the preference as a rule for the stronger patients because it is comparatively harmless for them and because the after-effects—if the ovaries are left—are decidedly less than with amenorrhea brought on by Roentgen-ray exposures. Necessity for rapid restoration of working capacity also compels operative treatment in many cases, so that radiotherapy will generally have to be reserved for well-to-do patients, but he who has beheld the brilliant effects of Roentgen-ray treatment in his own practice will certainly prefer it, they declare, in the suitable cases.

121. Raynaud's Disease.—In one of the two cases reported by von Hoesslin the vascular spasm involved, besides the extremities, the nose, chin and tongue. The trouble was ascribed to a severe chill which had been followed by rheumatic pains in the joints and swellings of the fingers and toes. The pains fluctuated in intensity and the tips of the fingers and toes varied from pallor to cyanosis. The involvement of the tongue permitted a number of interesting physiologic tests. In the second case the local symmetrical disturbances came on after an attack of influenza followed by a nodose arthritis; rheumatic pains were the first symptoms also in this case. The intense pallor in the face and hands first came on suddenly in consequence of fright from a lightning stroke near by.

127. Suprarenal Treatment of Osteomalacia.—Kownatzki reports a case in which a young woman in the fourth month of pregnancy developed osteomalacia rebellious to the usual measures; there was a slight enlargement of the thyroid. Under a course of suprarenal treatment she gradually recovered and was normally delivered although one thigh was left a little shorter. The question now is to determine in which cases of osteomalacia suprarenal treatment is liable

to prove efficient. It seems probable that the cases in which benefit may be anticipated are those in which the trouble is due to suprarenal rather than ovarian insufficiency. There are cases on record in which ovarian treatment proved successful and in certain experiments on animals thyroid treatment gave good results.

130. Chronic Continuous Excessive Secretion of Gastric Juice.—Schilling lays great stress in treatment on dietetic measures to refrain from stimulating the secretion, especially by abstention from salt. The beneficial influence of a salt-poor diet on the discomfort from hyperchlorhydria has been recently emphasized by Enriquez and Ambard. Rest is an important aid also for patients with engrossing occupations and who are growing thin. Milk gruels, chocolate, butter, cream, oil, toast and zwieback are the main reliance at first in treatment, supplemented later with cheese and soft eggs; meat is entirely prohibited and no salt allowed except a little for the gruels. In the third week a little pea or bean soup is permitted; tender mashed vegetables aid in satisfying hunger. All sweets are to be avoided as also raw fruit and coarse vegetables, alcohol, tea, coffee and tobacco. The patients take a hot bath twice a week. By the second month a little boiled white meat and fish is allowed and by the third month boiled beef, macaroni and marmalade. Roast meats and raw fruit must still be avoided for weeks after this. If the improvement is only moderate on this diet he repeats the course of dieting again after a six-week's interval. It is important to have the patient rest for a time after the noonday meal, and a daily walk should be ordered for brain-workers. These and other measures to tone up the nervous system are supplemented by a mixture of equal parts of silver nitrate and belladonna extract, 0.15, 0.2 or 0.25 gm. in 150 gm. water, taking half a tablespoonful in half a wineglassful of water three times a day before eating. A bottle of this lasts a week, and the first week the mildest strength is taken, two bottles of the second strength follow, and then two or three bottles of the strongest mixture, then reducing the strengths progressively backward in the same way, the whole medicinal course thus requiring 8 to 9 weeks. After completion of the dietetic and medicinal course he sends the patient away for a brief change of air. Treatment along these lines has not been entirely successful in every case but the results have always been encouraging. The symptoms subsided and the patients slept and felt well. If there was retention from the preceding day along with the hypersecretion, he relieved the patients by lavage of the stomach at bedtime, allowing a tranquil night or the nocturnal pains might be relieved by eggs, chocolate and milk. The flow of gastric juice might be checked by 2 or 3 tablespoonfuls of melted butter or oil morning and evening.

131. Treatment of Inherited Syphilis.—Halberstaedter and Reiche relate their experiences with 43 children with inherited syphilis tested for the Wassermann reaction before and after each course of specific treatment. The children were in a special asylum and constantly under observation. The experiences with the Wassermann reaction were similar to those observed in the tertiary phase of syphilis in adults, the reaction persisting positive with great tenacity. A negative reaction frequently became positive again without apparent reason. The children given systematic specific treatment have thriven and developed well and are free from symptoms even although the Wassermann reaction continues positive.

137. **Diabetes in Children.**—Lauritzen reviews his experiences with 27 cases of diabetes mellitus in children; an inherited taint was evident in 7, but no indications of pancreatic disease or trauma affecting the brain were discoverable in any instance. Next in importance to the regulation of the diet, he declares, is the necessity for mental and physical rest, reducing tissue waste as much as possible; massage should be given while the child stays in bed, and for this and other reasons, he considers institutional treatment indispensable for diabetes in a child, even in the mild forms. The aim should be to relieve not only the organs in charge of sugar metabolism of all unnecessary work but also all the cells. He insists on the importance of recognizing an incipient tendency to diabetes in children and that the children in families inclined to metabolic disturbances, gout, etc., and children with acne, boils, eczema and other skin diseases should be supervised with special care in this respect, examining their urine frequently. If any reducing substances are found in the urine, a test meal of rice, fish, potato and bread should be given and the urine for the following four hours collected and analyzed. If the glycosuria increases, dietetic restrictions should be enforced at once. Only when the diabetes is detected in its earliest phase can material improvement or a cure be anticipated. Diabetes in children under 2 generally runs a rapidly fatal course. In the mild cases it is important not to jeopardize all with too early resumption of a mixed diet. In the mild and moderately severe cases the patients should return to the hospital four times a year for revision of the assimilating capacity and degree of production of diacetic acid and acetone and have the diet regulated anew accordingly. In the severe cases not until the urine has been made alkaline or is still only slightly acid under large prophylactic doses of sodium bicarbonate is it safe to inaugurate the strict antidiabetic diet. If the glycosuria persists he keeps the child in bed and occasionally allows nothing but water for a day. He accepts the beneficial and apparently specific action of oatmeal in diabetes and makes much use of it, but he always precedes the oatmeal days with a strict albumin-poor diet for a few days, then an exclusively vegetable day, then the oatmeal for a few days, then two or three vegetable days, and then the strict albumin-poor diet again, although in the severer cases the resumption of the stricter diet must be very cautious as otherwise the acidosis may suddenly increase and coma follow. He gives the tabulated details of several cases to show the great benefit that may be derived from treatment on these principles, generally following von Noorden's technique. Eight of the children are still living, including a girl of 8 with intense acidosis when first examined a year ago. The duration of the disease was from 2 months to 4 years in the others. He emphasizes the fact that the total acidity and ammonia content of the urine parallel each other and are a useful index of the daily fluctuations of the acidosis. He classifies the cases as mild when the sugar rapidly disappears on a diet poor in carbohydrates, and moderately severe when the sugar does not disappear unless the diet contains so little albumin that there is only from 7 to 13 gm. of nitrogen in the urine. The proportion of albumin allowed in the diet should be that with which the urine is kept free from sugar, and the amount of food should be kept down to what is actually required.

138. **The Sudden Appearance of Apnea with Unconsciousness in Tabes.**—Jacobsohn reports a case which he says is similar to those reported by Hoover in THE JOURNAL, July 20, 1907, page 237. In all the cases on record of this suddenly appearing apnea with a semicomatose state the patients had

tabes, with a single exception, and in nearly every instance the attack followed administration of morphin or heroin as in his case. He accepts a temporary paralysis of the respiratory center as the cause of the trouble, and thinks that there is ground for nominating the morphin as a factor in the process. Pal regards the phenomenon as similar in its nature to intermittent claudication. Jacobsohn's patient is a tabetic woman of 46 who has been under observation for a year and a half and several of these respiratory attacks have occurred in its presence; they seemed sometimes to take the place of abdominal crises. In one attack a gastric crisis was followed at once by unconsciousness for 45 minutes, and during this time the respiration stopped ten times for from 60 to 80 seconds at a time. One day there were two attacks lasting 4 minutes each, followed the next day by unconsciousness for several hours with frequent pauses in breathing lasting from 2 to 4 minutes. The heart and pulse rate were not modified during the attack, the heart working powerfully as usual. As a rule cyanosis became evident about the end of the second minute, in another minute there was clonic twitching in the legs, then the respiration started up again full and deep and the patient regained consciousness.

140. **Treatment of Whooping Cough.**—Bradt ascribes the symptoms of whooping cough to a local process in the upper air passages and declares that local treatment of the nasopharynx is frequently able to arrest the syndrome. He uses a mixture of iodine and phenol 0.5 parts, with 1.5 parts potassium iodide and 15 parts glycerin in 100 parts water; with this he swabs the nasopharynx for 2 or 3 seconds once a day. This local treatment is supplemented by keeping the child in out door air as much as possible.

142. **Sugar Content of the Cerebrospinal Fluid in the Insane.**—Hess and Pötzl report 16 cases of mental disease in which the proportion of sugar in the cerebrospinal fluid fluctuated within wide limits, sometimes in the same patient at different times. These fluctuations were noted in cases in which there was nothing to suggest an inflammatory process. The list included cases of dementia praecox and epilepsy.

147. **Test for Ammonia in the Urine as Index of Diabetic Acidosis.**—Marcovici gives the details of the simple Ronchese test based on the action of formalin on the ammonia salts. A 10 per cent. solution of sodium carbonate is added, a drop at a time, to the urine until the reaction becomes neutral. The formalin (40 per cent.) is neutralized with a one-fourth normal soda solution against phenolphthalein until a slight pink tint develops. Then 25 c.c. of the neutral urine and 10 c.c. of the neutral formalin are mixed and titrated against decinormal soda solution until a deep pink develops. The calculation is simple: 1 c.c. of the decinormal soda solution for 100 c.c. of urine corresponds to 0.017 gm. ammonia in 1,000 c.c. of urine.

- 148 *Spengler's I. K. in Surgical Tuberculosis. A. Exner and R. Lenk.

148. **Inefficiency of Spengler's I. K. in Surgical Tuberculosis.**—This communication from the university clinic at Vienna in charge of Hocheneegg reports the application of I. K. in a number of cases of surgical tuberculosis with disappointing results. In 6 of the cases more than 6 months has elapsed since this treatment was commenced and the influence seemed to be rather deleterious. One woman with tuber-

culous peritonitis and enteritis, with slight fever, died from miliary tuberculosis 2 months after commencing the I. K. treatment. In a case of bilateral tuberculosis of the testicles and slight apical lesions, the lesions in the testicles seemed to show improvement under the I. K. at first, but the apical lesions progressed to florid phthisis and the patient succumbed 8 months after the beginning of the five-months course of treatment. In none of the other cases was any appreciable influence from the treatment discoverable and the use of I. K. has been abandoned.

- 151 *Acute Peritonitis Presumably Originating in the Genitalia. G. Pallin.
152 *Systematic Tampon Drainage of Small Pelvis in Prevention of Postoperative Peritonitis. E. Schürmann.

151. Acute Peritonitis of Non-Puerperal Genital Origin.—Pallin is convinced that it is more than a mere coincidence that only one patient was a man out of his 7 patients with peritonitis of obscure origin during the last 5 years. In 4 of the women the symptoms developed with a menstrual period and the fifth had not commenced menstruating again after a childbirth. Pathologic changes in the adnexa were evident in only 2 of the women; the appendix was apparently sound in all. Nützel found a gynecologic origin in 43 out of 241 patients operated on for peritonitis, and Hagen has reported 3 fatalities in a group of 7 of gynecologic origin. He emphasizes the grave prognosis and the injurious influence of menstruation. From these and other data Pallin concludes that acute peritonitis may develop from the female genitalia alone, and that the infection may reach the peritoneum through the tube without causing inflammation on the way.

152. Systematic Tamponing of Small Pelvis to Prevent Peritonitis.—Schürmann declares that postoperative peritonitis is far too common and that more vigorous measures are needed against it. The main source of trouble, he is convinced, is the actual contact of the intestines with the oozing pus in the operative area. A small strip of gauze laid over the suture is pushed along by the intestines as they slide back into place after a laparotomy; this leaves the suture bare so that intestines and peritoneum rest against it and become infected. In order to prevent this he systematically packs the entire small pelvis full of gauze before lowering the pelvis after the operation. Then when the intestines slide down they rest on the gauze and are saved from infection. Any infectious process developing in the operative area remains localized here. In case the whole pelvis has been contaminated, he supplements this tamponing by tamponing through the abdominal incision, packing the pelvis with gauze so amply that the intestines are not able to slide down into the small pelvis at all. Ordinary drains are unable to convey all the secretions away; even with the best gauze drainage pus was found still clinging to the suture whenever he was obliged to open the abdomen again for any reason. It was formerly believed that the great absorbing power of the peritoneum was able to protect it against the spread of infection, but recent research has failed to disclose bacteria in the circulation, such as would be found if the peritoneum absorbed them as assumed. On the other hand, the lymphatics in the peritoneum have been found clogged with a copious cellular and fibrinous exudation, and this is now regarded as the natural defensive mechanism. This walling off is realized further by the adhesions induced by the mechanical irritation from the gauze tamponing, besides the direct protection afforded by the gauze itself. He does not use medicated gauze exclusively, on account of the danger of intoxication.

A CRITICISM OF THE BLOOD-PRESSURE APPARATUS*

C. F. HOOVER, M.D.
CLEVELAND

The sphygmomanometer is generally assumed to be an instrument which enables us to measure the maximum and minimum endovascular arterial pressure. If this assumption is true, it does not follow that we have any data on which to estimate the mass movement of blood, the real problem that remains to be solved in the study of cardiovascular diseases. In subjects with a normal vascular system the blood-pressure apparatus gives us reliable information about the maximum systolic pressure. But in clinical experience it can be shown that the blood-pressure apparatus gives misleading information even on this basic point. The diastolic blood-pressure can be measured about as accurately as the systolic blood-pressure. But the diastolic endovascular pressure is not a measure of the systole of an artery. In other words, we may have the equivalent of a normal diastolic pressure and the artery remain full of blood during the cardiac diastole.

We are perfectly familiar with stasis in the centrifugal stream with high diastolic pressure as seen in chronic interstitial nephritis, but I doubt if it is generally recognized that we may have the equivalents of normal systolic and diastolic pressures and still have a marked stasis in the centrifugal blood-stream.

ESTIMATION OF DIASTOLIC PRESSURE BY SPHYGMOMANOMETER CONTROLLED BY PALPATION OF ARTERIES

Another point of interest I wish to discuss is the manner of estimating diastolic pressure in an artery and the reason for its reliability. Since the sphygmomanometer has been devised there seems to be a very general concession by clinicians that endovascular blood-pressure can be estimated only by instrumental means and that the older method of relying on the fingers is inaccurate and misleading. The source of error does not lie so much in the sense of touch as in the choice of the artery from which the estimate is made. I readily admit the impossibility of making an accurate estimate of blood-pressure from the radial or even the brachial artery. The only artery which serves this purpose is the femoral artery. The reason for this is very apparent. The femoral artery at Poupart's ligament is very accessible and lies on the pubes against which the artery can be compressed. Here we have an artery which gives us practically the lateral pressure in the abdominal aorta and lies under the mastery of the finger. When we palpate an artery, we do not feel the endovascular

pressure, but we really feel the bursting tension of the arterial wall. The bursting tension on the walls of a hydraulic tube is equal to ΠR times the pressure, that is, 3.1416 times the radius of the tube multiplied by the pressure. This result is obtained by multiplying the circumference of the tube, which is $2 \Pi R$ by the known pressure per centimeter square and then dividing the result by two. The product of the circumference and pressure must be divided by two, because the bursting tension would be equal to the pressure on one side only of any given diameter of the tube. Therefore, ΠR times the pressure equals the bursting tension in any artery.

If pressure remains constant, the bursting tension will vary directly as the radius of the artery. If we now assume the femoral artery to have a radius four times that of the radial artery, it is quite apparent that any variation in pressure will be magnified four times in estimating the bursting tension of the femoral artery as compared with the bursting tension in the radial artery. This is analogous to the comparison between a microscopic view of 200 diameters and a microscopic view of 50 diameters. During the past four years it has been my practice to estimate the arterial pressure by palpating the femoral artery and afterward to use the blood-pressure apparatus. A little practice will enable one to estimate the blood-pressure very accurately. In pressures between 150 mm. Hg and 250 mm. Hg I find that there is rarely a disparity of more than 20 mm. between the digital and instrumental estimate, and as a rule the disparity is within 10 mm.

RESISTANCE OF ENDOVASCULAR BLOOD-PRESSURE AND HYPERTONIC VASCULAR WALLS TO PNEUMATIC CUFF

When very high pressures are recorded by the sphygmomanometer, the question has been raised as to whether the resistance offered the pneumatic cuff really represents endovascular pressure or the resistance of a hypertonic arterial wall plus endovascular pressure. The fact that supposedly high blood-pressures are often tolerated for years and with so little evidence of myocardial enlargement compels us to respect this criticism; but, on the other hand, when we have opportunity to study great oscillations of blood-pressure in a patient it seems very improbable that the resistance offered by the femoral artery should consist in wall resistance and the artery vary so little in volume during the periods of high and moderate pressure.

A year ago a patient at Lakeside Hospital had a blood-pressure which varied from 180 mm. Hg to 350 mm. Hg. These periods of hypertonus would last for several successive days and then subside. When the pressure registered as high as 350 mm. Hg in the arm, the resistance in the femoral artery was enormous. When the pressure would again descend to 180 mm. Hg the

* Read in the Section on Practice of Medicine of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

femoral artery would feel slightly larger, but the difference in caliber could not have been great, for the variations in size of the femoral artery gave no hint of the change in pressure. If this great change in resistance of the arterial wall was due to resistance of a hypertonic wall and not to endovascular pressure we certainly had reason to expect great changes in the caliber of the vessels. This is always true in smaller arteries like the radial, where the proportion of muscular tissue in the arterial wall is much greater than in the femoral artery.

Since the arterial blood-pressure has been a subject of extended clinical observation, it has become apparent that either high endovascular pressure does not tax the heart so severely as we formerly believed or our measurements have been misleading, in so far as they have led to inferences regarding expenditures of energy in the output of the left ventricle.

REPORT OF CASES

CASE 1.—During the past winter a woman 50 years of age, who came under my observation, presented a very interesting problem in arterial pressure. The patient had not yet passed the menopause and had the appearance of being in good health. There is nothing in her family history or personal history which has any bearing on her present disability, except that the patient had always been a rather nervous person and for five years prior to the development of her first symptoms (which occurred eighteen years ago) she endured a great deal of worry and anxiety on account of the death of her husband and legal entanglements of his estate. Three years before the present attacks began, she found that in playing the piano her forearms became numb with a sense of tension, which was so uncomfortable and so persistent in its occurrence that piano-playing had to be abandoned. Fifteen years ago the first attacks of angina began. The pain begins between the shoulder-blades and runs about both sides of the thorax to the precordial area, and, when severe, runs down the inner side of both forearms. It is particularly severe in the right arm. These attacks of pain are accompanied by a sense of cardiac palpitation and eructations of gas from the stomach. The eructations of gas are not, however, followed by any sense of relief. After the attacks there is a peculiar feeling of numbness in the hands, particularly in the right hand. Both hands are then hypersensitive to both heat and cold. There is never any dyspnea on exertion, although exertion will bring on the attacks of pain. Eating a large meal will produce the attacks, and often the patient is wakened out of a sound sleep by the pain. The patient's appetite is good, the bowels are slightly constipated.

The urine showed no indications of any renal involvement. There were no signs of any kind brought out on physical examination which betrayed any alteration of reflexes or any change in afferent or efferent nervous impulses. All diseases of the brain and cord or peripheral nerves could be excluded. The lungs, mediastinum, liver, spleen and alimentary tract revealed no signs of disease. The eye-grounds were normal.

The left border of the heart in the fifth interspace was 12 cm. to the left of the median line and the right border of the heart at the third interspace was 3 cm. to the right of the median line. The upper border of the heart was at the top of the third rib in the left parasternal line. The left border of the heart was not sensitive to direct percussion. I mention this because we very commonly find in the early stages of cardiovascular disease, when the myocardium begins to show some sign of distress, that the external border of the heart is marked by tenderness to direct percussion. This tenderness is not present in cardiac enlargement due to Basedow's disease, for in the early stages of Basedow's disease the cardiac enlargement is not associated with any impairment in the mass movement of blood. This tenderness is not present in cardiac enlargements of long standing, when due to either valvular or myocardial disease.

In our case, therefore, there was not a single sign of any kind which would indicate any impairment in the mass movement of blood. When the patient entered the hospital, there

was perfect consistency between the feel of the femoral artery and the blood-pressure as registered by the sphygmomanometer applied to the arm.

The maximum systolic blood-pressure on entrance was 235 mm. Hg. The patient remarked that she had caused the bursting of every blood-pressure apparatus which had been used on her. The blood-pressure was first measured about two years ago and was then found to be 350 mm. Hg. The same high record was made by several physicians at different times. The highest pressure found during the patient's three weeks' stay in the hospital was 245 mm. Hg. Relief from the attacks of angina has invariably followed immediately after taking 1/100 grain of nitroglycerin. The pains were so severe and relief followed so promptly from the use of nitroglycerin (which was always at hand) that we never had the opportunity to measure the blood-pressure during an attack, but I think it is fair to assume there was a marked rise in blood-pressure during the attacks of angina.

On February 18 the following experiment was made with nitroglycerin to see how much the blood-pressure could be lowered with nitroglycerin. A 1 per cent. alcoholic solution was used and the liquid was dropped on the tongue from a medicine-dropper.

Time, P. M.	Dose, Drops.	Pulse.	mm. Hg B.P.
9:30.....	1	75	215
9:32.....	1	72	224
9:34.....	1	76	224
9:36.....	1	81	238
9:38.....	1	81	238
9:40.....	1	84	234
9:42.....	1	84	234
9:44.....	1	81	208
9:46.....	1	81	208
9:48.....	2	81	162
9:50.....	2	78	162

In twenty minutes there were thirteen drops of a 1 per cent. solution of nitroglycerin given which was well tolerated. Nothing more than a slight sense of fullness in the head was complained of. The patient had the best night's sleep she had had for many weeks. The blood-pressure in the arm was never again as low as 162. This shows, however, that sclerosis of the artery could not have been a factor in resistance to the pneumatic cuff. There was no palpable thickening of any of the accessible arteries. An ophthalmic examination revealed no abnormality in the retinal nerve-heads or retinal vessels.

As soon as it was once learned that the blood-pressure could be reduced by the use of trinitrin without causing discomfort or any untoward symptoms, one drop of the 1 per cent. solution was given every hour and the dose was gradually increased in the course of three days to 5 drops every hour. The blood-pressure chart showed no alteration. The pressure was taken from the right arm every four hours. I then palpated the femoral artery and found the pressure nearly normal in that artery. The cuff was then applied above the ankle of the right side and the dorsalis pedis artery used for control. The artery was of fair size and quite as suitable for the purpose as the radial. Here the maximum pressure was only 160 mm. Hg. The blood-pressure apparatus nearly always gives a higher registration when applied to the leg, so it seems fair to assume that this measurement would be consistent with an arm measurement in the average normal subject of about 20 or 30 mm. less. The cuff was then applied to the left arm and the pressure measured there was slightly less than in the right. Here is a patient with a history of vasomotor angina with blood-pressure of 245 in the arms and 160 in the legs after trinitrin had been given in large doses. The pressure in the femoral arteries prior to the administration of nitroglycerin was consistent with the pressure in the arms; now, however, the femoral and brachial arterial pulses did not feel as though they belonged to the same person.

If it is possible to have widely differing blood-pressures in branches of the aortic system, then it is apparent why this patient, whose brachial pressure was so high for two years (of which we know), revealed no signs of distress in the heart. If the splanchnic arterial distribution constantly maintained the same low pressure, compared with the accessible arteries, as the femoral

artery now shows, compared with the brachial, then, it is quite apparent that the brachial pressure did not habitually represent the pressure in the thoracic aorta and for this reason the myocardium showed no signs of distress after years of supposedly high pressure.

Another explanation of myocardial preservation under such conditions was suggested by the history of another patient who was first seen in 1905.

CASE 2.—The patient, a man, then 35 years old, had marked cardiac hypertrophy, high arterial pressure and pulmonary edema. Rest in bed, milk diet, warm baths and nitroglycerin gave him great relief. After a month of this treatment he left the hospital and was not seen again until four and a half years later, in 1909, when he again presented himself with the same symptoms, although not quite so severe as four and a half years before. It was then learned that he had continued uninterruptedly at his vocation of barkeeper, that he had been quite comfortable during all that period, and that he had taken nitroglycerin for only a few weeks after his first stay in the hospital. We then found that his blood-pressure on waking in the morning was only 130 mm. Hg, and in half an hour it would again be 190 mm. Hg, where it obstinately remained in spite of the use of nitroglycerin. There was never any disparity between the feel of the femoral pulse and the brachial pulse in this man, but the pressure in the leg was not taken with the instrument. It was found later that if the blood-pressure was taken immediately when the patient awoke from a short nap of thirty minutes, it was only 130 and regained its original point of 190 about one-half hour after waking. These observations were made repeatedly in this man on waking in the morning and on waking after short naps and the results were always the same.

This patient, therefore, had an arterial hypertonus when awake, and vascular relaxation when asleep. What preserved him so long against myocardial exhaustion was the slumber relaxation. This amounts to a very great compensatory measure in a man who gets nine hours' sleep every day. To return to the first patient, however, it was found that she did not at any time have a lowered blood-pressure on waking; and furthermore her attacks of angina often came on during sleep; consequently, we can eliminate slumber relaxation as a compensatory measure in her case.

The other problem which presents itself is whether the patient really had such widely differing pressures in the femoral and brachial arteries or whether the hypertonus of the artery offered the resistance to the pneumatic cuff. Were we really measuring resistance of a hypertonic arterial wall and not endovascular blood-pressure? Three resident physicians at Lakeside and I tried exposing an arm to extreme cold to see if the pressure in the exposed arm differed from the pressure in the other arm which was not exposed to cold. The experiment was made in the following manner:

The person under observation lay flat on a table with a trough of ice-water at his side. A blood-pressure apparatus was applied to the left arm and to the right arm at the same time and the pressure recorded. Then one arm was laid in the ice-water and, when the arm became painful from extreme cold, the pressures in both arms were recorded. In the other three men there was no essential change, but in my own case there was a marked rise in pressure in the cold arm and no rise in the other arm. The pressure in my right arm was 136 and in the left arm 126. Then the right arm was laid in the ice-water so that the upper arm as high as the top of the cuff was covered. When the arm became very painful, the pressure in both arms was measured. The left arm recorded 126 as before but the maximum pressure in the right arm was 158, a rise of 22. There could have been no error in palpating the radial artery, because I could tell the instant the least trickle of blood passed beyond the cuff by the feel of the water-hammer jet, which could be perceived equally well when the arm was

in and out of the water. The instant the arm was lifted out of the water and the pain ceased, the pressure was again lowered to the original point of 136.

On another occasion I tested my blood-pressure much in the same manner, but under different conditions. The early part of the day from 9 to 11.30 a. m. was occupied, in making a ward visit, from 12 to 2 p. m. was occupied with writing, then a moderate luncheon, at which two cups of tea were drunk, was followed by smoking one cigar. An hour later the experiment was made. The pulse-rate was 72 per minute. A blood-pressure apparatus was applied to each arm and the records were made by two resident physicians. One man watched each apparatus and recorded their results independently of one another. Before the right arm was put in the ice-water the maximum systolic and diastolic pressures, respectively, were 170 and 133 in the right arm and 168 and 132 in the left arm. The femoral artery was then palpated by Drs. McLaughlin and Boyer (who are experienced in estimating blood-pressure) and both agreed that, when the one arm was put in cold water, a decided rise in pressure was perceptible, which was consistent with the records made by the instrument. Several trials showed a rise to 180 in the chilled arm. It does not seem likely that the rise in pressure was due to pain, for, though the three other men experienced quite as much pain, their pressures did not rise after exposure to cold. On both occasions when the observations were made, the exposures to cold were made repeatedly. On the first occasion there was a rise only in the chilled arm and none in the other arm. The second trial showed a consistent rise in all accessible arteries. The rise was both in the systolic and diastolic phases. The disparity between the pressure in different arteries in the case of one patient was apparent only after trinitrin was used in considerable dosage, but this disparity was confirmed by repeated examinations during a period of a week. The differing results in my own experiments with the cold water were just as certainly established by repeated measurements.

Whether there were really different endovascular pressures in the several arteries, or different degrees of hypertonus in the arterial walls which gave the results, the deduction remains the same, namely, that the blood-pressure apparatus applied to accessible arteries does not give infallible information as to the aortic blood-pressure and, as a consequence, it is not safe to rely on routine measurements from the arm as a guide to the employment of vasodilators in treating patients with high arterial pressure.

The maximum systolic and minimum diastolic pressures may be within the normal limits and still the mass movement of blood be much impaired. Recently I observed a ward patient at Lakeside Hospital who had pronounced cardiac dilatation and tricuspid insufficiency, as evidenced by dilated jugular veins with a systolic centrifugal pulse, which was plainly seen in the jugular veins and was distinctly palpable in the liver, which was enlarged a hand's breadth below the costal border. The patient had general edema and very marked cyanosis and orthopnea. The pulse-rate was 90, the maximum systolic pressure in the arm was 135 and the minimum diastolic pressure 96. That there was a severe alteration in the mass movement of blood in this patient was clear enough from the cyanosis, dyspnea, venous and hepatic pulsations and edema of the lower extremities.

Although the maximum systolic and minimum diastolic pressures were equal to those we often find in patients with a good mass movement of blood, palpation of the arteries revealed an artery filled with blood during the diastolic phase. There was, then, an increased resistance in the peripheral arterial distribution and stasis in the centrifugal arterial stream without an elevation in either the systolic or diastolic pressure. With

these arterial conditions, then, there must be a small ventricular output with each ventricular systole. A very small ventricular output is sufficient to elevate the pressure to moderate height (135 mm. Hg) in an arterial system which is full of blood at a moderate pressure during the cardiac diastole. This patient's myocardium was the factor which was chiefly at fault in the circulatory system. As a rule, patients with an increased peripheral resistance in the arterial system have high systolic and diastolic pressures, but, when the myocardium becomes inefficient at the same time that the increased arterial resistance develops, the systolic and diastolic pressures remain the same as in health, but the mass movement or minute volume of blood is greatly diminished.

If reliance is placed on the blood-pressure during systole and diastole, as a guide to the state of the circulation one can be greatly misled, for the pressure measurements are of value only when they are contemplated in the light of other evidence, which must be gained by observation.

DETERMINATION OF MINIMUM DIASTOLIC PRESSURE BY BLOOD-PRESSURE APPARATUS

Finally, I wish briefly to discuss the blood-pressure apparatus as a means of determining the minimum diastolic pressure. The two methods employed are (1) to find the pressure-point in the pneumatic cuff at which the mercury column has a maximum excursion, and (2) to find the point at which the sound heard distally to the cuff, suddenly diminishes in intensity, as the pressure in the cuff is gradually lowered. The first method is much less satisfactory than the second method. It is the second method which has some points of interest in the physics of the arterial circulation. If the brachial artery is compressed against the inner surface of the humerus, and the bell of a stethoscope is applied over the artery a short distance below the point of compression, there will be, of course, no sound audible so long as the artery is obliterated during cardiac systole. On diminishing the pressure so that a jet of blood escapes under the compressing finger, there will be a murmur and sound audible during the heart's systole, but the murmur predominates and often the sound is scarcely perceptible with the murmur. If a pneumatic cuff is applied and the pressure in the cuff is diminished so that a jet of blood escapes under the cuff during systole, but not during diastole of the heart, the relative intensities of murmur and sound are reversed. The sound, which is very like the "pistol-shot" tone, is loud and the murmur is faint. In many cases the murmur is not audible and only the pistol-shot tone is heard. If the femoral artery is compressed at the pubes, the so-called stenosis murmur is very loud and the pistol-shot tone is not heard at all. If one compresses the femoral artery, however, and then very cautiously relaxes the pressure so as to permit the very smallest possible jet to escape under the finger a pistol-shot tone is heard unaccompanied by a murmur, but, unlike the case with the brachial artery, when a larger jet is allowed to escape by relaxing the pressure a very little more a loud murmur is heard without the pistol shot tone. The sharply defined pistol-shot tone is heard only a short distance below the cuff or compressing finger in all instances.

The conformation of the jet seems to determine whether a murmur or pistol-shot tone will predominate. Flat compression of the artery gives, in all probability,

a different contour to the narrowed lumen from that procured by the circular pneumatic constriction. In the latter case the compression is applied in a number of different radii, whereas, in the former case, only a narrowed chink can be formed. Probably, as the constricted lumen more nearly assumes a circular contour, the water-hammer effect is more in evidence and the murmur is wanting. When the pneumatic cuff is used, in many cases only a pistol-shot tone is heard and no trace of a murmur is heard. When the brachial artery is compressed by the finger, a murmur is always audible and predominates, whereas the pistol-shot tone is comparatively faint.

Another point about this pistol-shot tone is of interest. Suppose we have a maximum blood-pressure of 150 and a minimum pressure of 100. The pistol-shot tone below the constricting band will have attained its maximum, when the cuff pressure is at about 145, and will remain at the same intensity until the pressure in the cuff is just high enough to prevent the escape of fluid during the heart's diastole. Then when the pressure in the cuff is no longer high enough to shut off the centrifugal flow during diastole of the heart, the sound becomes faint, so that the pistol-shot tone will grow faint immediately when the cuff pressure goes below 100. The pistol-shot tone is due to the escaping jet of blood and not at all to the excursion of the collapsed arterial wall below the cuff. As the pressure in the cuff is diminished, the arterial lumen under the cuff increases; consequently, with a diminishing pressure in the pneumatic cuff the volume of the jet increases, but the velocity will diminish. Therefore, the mass times the velocity in the jet remains constant, until a point is reached at which a null pressure in the artery distal to the cuff no longer exists during cardiac diastole, and then the difference in pressure, above and below the cuff, is no longer great enough to produce the water-hammer effect.

I attempted to reproduce these phenomena by inserting a cannula in the subclavian artery of a fresh cadaver. The radial artery was opened and the cuff of a blood-pressure apparatus applied to the arm. Liquids of varying specific gravities were pumped through the artery, when the pressure in the pneumatic cuff was at varying points from 120 to 300 mm. Hg, but the pistol-shot tone could not be produced and the pulse of the jet of liquid, as it shot beyond the constricting cuff, was very different from the pulse of the jet of blood during life. Instead of the high velocity with which the jet of blood during life shoots under the cuff, there was a lazy rise and fall in the pulse below the cuff. No pistol-shot tone was heard; nothing but a murmur was audible with all the pressures and kinds of impulses we were able to give the jet of liquid. It would evidently require a nicely constructed power-pump to produce the same kind of jet which occurs in the blood-stream during life.

When air instead of liquid was pumped through the artery, the velocity of the jet was of course much greater and the pistol-shot tone immediately below the cuff was very loud. When a bandage was drawn about the forearm at the same time that air was pumped through the artery, the intensity of the pistol-shot tone diminished, as very slight pressure was applied by the constricting bandage. As soon as the pressure of air in the artery between the cuff and the bandage no longer sank to zero between the impulses from the pump, the pistol-shot tone diminished in intensity.

When the brachial artery immediately below the cuff was exposed and opened and traction applied by means of two forceps so as to eliminate the factor of excursion of the arterial wall, the pistol-shot tone below the cuff remained the same as before.

CONCLUSION

I do not wish to discourage the use of the blood-pressure apparatus. It is a very valuable instrument, but its chief value consists in teaching us how to palpate the arterial pulse. No instrument can take the place of the finger, nor can any instrument teach as much about the pulse as can be learned by palpation.

ABSTRACT OF DISCUSSION

DR. JUDSON DALAND, Philadelphia: We owe Dr. Hoover a debt of gratitude for calling attention so plainly and definitely to the facts, not generally remembered, that the blood pressure varies at different times of the day, and more particularly, in certain cases, and that there is a difference between the blood pressure in the waking and sleeping states. Again, the mere application of the pneumatic cuff in certain neurotic subjects often increases the blood pressure as much sometimes as 30 or 40 mm. Often the fainting patient will permit of a true reading. Observation systematically made will show in many instances a temporarily extraordinary increase in the blood pressure. Therefore, it seems to me that we should bear in mind that variations occur in many cases. The case reported by Dr. Hoover, so far as I know, is a very unusual one; I have no recollection of any such experience in my practice, nor do I recollect any such extraordinary disparity between the blood pressures of the inferior and superior extremities. So far as the determination of the blood pressure by means of the finger applied to the radial artery is concerned, I have found that in about three-quarters of the cases I can estimate approximately the blood pressure; but in the remaining 25 per cent. I am at sea. We should thank Dr. Hoover for calling our attention to the femoral artery where manifestly there is offered a physical condition vastly superior to the radial artery.

THE PATHOLOGY OF MASTOIDITIS AS REVEALED BY THE X-RAY *

SIDNEY LANGE, M.D.

Lecturer on Radiology in the Medical Department of the University of Cincinnati
CINCINNATI

The x-ray study of the mastoid region, which was begun in March, 1908, has undergone a slow but gratifying metamorphosis. Undertaken with grave doubts as to its practical value, it has developed into a method which rivals in its accuracy other recognized methods of physical examination.

At the inception of the work, it promised at best to show the anatomy and the grosser chronic changes in the mastoid region. Then the graver acute changes were registered on the skiagram, and later it was found that the milder acute mastoid affections yielded roentgenologic evidence of their presence. Within the last few months it was discovered that in acute otitis media without clinical signs of mastoid involvement, the x-ray would often show clouding and filling up of the mastoid cells just back of the antrum, which changes may either

recede or progress as the patient either recovers, or goes on to what is clinically termed mastoiditis. The x-ray method is presented then as a method of studying *intra vitam* the gross pathology of the mastoid.

A correct roentgenologic technic is, of course, the *sine qua non* in this work, and all conclusions should be based upon technically good plates. The method employed for correctly skiagraphing the mastoids was presented before this section one year ago.¹ Further details of the x-ray technic were outlined by me in a previous paper² and need not be repeated here. In no instance has a technically good plate failed to give valuable and accurate information. Barring those uncommon cases in which the cortex over the mastoid is excessively thick, or in which the mastoid cells are poorly developed, the x-ray method should in every case reveal in a gross way the pathologic status of the mastoid process.

The question of excessive distortion of the relations of the mastoid as a result of the obliquity of the rays was answered by making a series of tests on the dried skull. Lead markers were placed on the tegmen, groove for lateral sinus, and mastoid tip, and measurements made from the skiagraph were compared with the actual distances. In no instance did the discrepancy exceed 3 mm., which difference for practical purposes may be disregarded.

My interpretation of the skiagram is always based on a comparison of the diseased with the opposite normal mastoid. After repeated comparisons, in normal individuals, in no case did I find essential differences between the two normal mastoids of the opposite sides. While there may be variations in the size, number and arrangement of the cells of the two sides, the mastoids as a whole were closely similar in type. That is, if there is a pneumatic mastoid on one side there will be a pneumatic mastoid on the other, or if the one mastoid is of the diploetic type the opposite one will be of the same type. Plageman says "On a basis of 85 skiagrams of normal skulls, we find that as a rule the two mastoid processes of healthy individuals are almost identical." Where both sides are diseased more difficulty is encountered in reading the plates, but after a study of many plates a fairly accurate interpretation may be made of a single plate without a comparison with its fellow of the opposite side.

Previous inflammation in a mastoid usually leaves permanent alterations in the bone, either in the form of more or less extensive absorption of the mastoid process or sclerosis of same, and if this inflammation occurs in early life the development of the mastoid may be so retarded as to result in a diploetic or even sclerotic type. Therefore, in interpreting mastoid plates the previous aural history must be ascertained.

On the mastoid skiagrams of children under 10 years the mastoid appears entirely spongy or diploetic, there are few visible cells, and the tip is undeveloped. The tip at this time consists simply of an inner and outer table, with little cancellous bone between, and shows little structure on the skiagram. From the age of 10 to 15 the mastoid takes on the pneumatic characteristics: large cells appear and grow downward toward the tip, its diploetic structure finally giving way to the more or less pneumatic adult type. The development of the mastoid may be beautifully demonstrated by a series of successive skiagrams.

* Read in the Section on Laryngology and Otology of the American Medical Association, at the Sixty-first Annual Session, held at St. Louis, June, 1910.

2. Am. Quart. Roentgenol., December, 1909, No. 1, ii.

In order to study the mastoid relations more graphically, stereoscopic skiagrams may be made. For this purpose, I have devised a small stereoscopic platform by means of which the two stereoscopic exposures may be made on a 5 by 7 plate. When developed and dried this plate may be placed directly without printing or reduction in a cheap parlor stereoscope and viewed by transmitted light. This method has not been used as a routine, because of the fact that four exposures (two for each mastoid) are required. A reluctance to make repeated exposures has interfered also in following the clinical cases at various stages from onset to cure. While the danger of the temporary Roentgen alopecia is a remote one, even though the exposures be repeated, provided an aluminum and leather filter be used, it was thought best not to take the chance of embarrassing the work at this time by any such untoward after-effects. Therefore, in most of the patients examined but one exposure of each side was made. Just one caution should be given in regard to the character of tube best suited to this work. The lowest or softest tube possible should be employed. The higher tubes give crisper and more beautiful pictures, but when we consider the small size of the mastoid cells and the fact that we are attempting to show all the smallest septa and contents of these cells, those tubes which give beautiful bone detail of the heavy cranial bones will often fail to show the slightest changes in density in the mastoid region.

CLASSIFICATION OF PATHOLOGIC CHANGES

The pathologic changes which may be noted on a skiagram may be tabulated as follows:

1. Slight haziness of cell spaces or complete filling of same with something denser than air. These changes represent clinically otitis media with slight mastoid involvement and the milder forms of mastoiditis. The something which fills the cells is in all probability serum. To show these slight changes the skiagram must be made with a soft tube and slightly underexposed.

2. Marked clouding of cell spaces with loss of distinctness and partial destruction of cell walls. Clinically these changes are found in the more severe grades of mastoiditis with pus formation and bone softening.

3. More or less complete loss of structure of the mastoid process occurring (a) either in the form of localized abscess formation, or (b) as is often seen in the subacute cases in the form of diffuse loss of structure, indicating advanced necrosis of the entire mastoid process.

4. Increased bone density of the mastoid process with (a) partial or complete obliteration of cells and (b) with or without bone defects. This class represents the chronic sclerosed cases.

These changes will be discussed in the reverse order, the order in which they are recognized.

CHRONIC MASTOIDITIS

The first report of this work was based entirely on the examination of the chronic cases. The ease with which chronic changes can be shown on the skiagram offers a method of determining in any case of chronic otorrhea the gross pathologic condition of the mastoid process. In those cases in which the cause of the continued discharge cannot be determined by the usual methods the skiagram may give the desired information by showing the extent of the sclerosis on the one hand or gross bone defects on the other.

The skiagraphic appearance in these cases is a thickening and obliteration of cells. In older cases the entire

mastoid process appears dense and structureless, giving no indication of the presence of cells. From my experience it would appear that this extensive sclerosis occurs frequently after mastoiditis of a mild and not necessarily long-continued type, since the sclerosing process is a healing process. Interesting to note is the fact that, in the examination of supposedly normal cases for purposes of study, every now and then a markedly sclerosed and often undersized mastoid process would be found, and no history of previous ear trouble could be elicited from the patient. These undersized sclerotic types probably represent a sclerosis, partial absorption or retardation of mastoid development, consequent on a forgotten otitis media of early childhood. Aside from these occasional exceptions in all of the markedly sclerosed cases the patients examined had symptoms in the form of intermittent otorrhea. To illustrate different phases several cases will be cited briefly.

CASE 1.—*Sclerosis*.—A. V., aged 16, presented intermittent discharge from the left ear dating from an attack of acute otitis media three years back. Examination revealed a thickened drum with a small perforation in the antero-inferior quadrant. X-ray examination showed a sclerotic mastoid on the left side, with very little evidence of cellular structure. Subsequent operation verified the x-ray findings. This history is typical of a majority of chronic cases encountered.

CASE 2.—*Sclerosis with Bone Defect*.—J. Z., Italian, was admitted to the Cincinnati Hospital because of some pain and tenderness over the mastoid. Previous history could not be obtained, except that the affected ear had discharged for some time. Examination of the canal revealed changes associated with chronic middle-ear suppuration. An x-ray examination of the mastoids showed no cells on the affected side. Instead, the bone seemed to be hollowed out just back of the antrum. On operation, no cells were found, but a large bone defect in a small sclerotic mastoid.

CASE 3.—*Subacute Case with Bone Softening*.—This is a subacute rather than a chronic case, but is included here because the plate showed typical bone defects in a thickened mastoid, such as might be encountered in the more chronic cases: Mr. C., aged 35, came in from one of the surrounding towns because of continued discharge and pain over the mastoid dating back seven weeks. The case had received practically no treatment. Examination showed a perforation in the anterior inferior quadrant. No bulging of the canal. Temperature was 99.5 in the evening, normal in the morning. Pain was marked especially at tip. The patient was referred to me for x-ray examination, which revealed an apparently thickened and structureless mastoid except for several irregular areas of apparently more necrotic bone which seemed to honey-comb the mastoid. Operation the following day substantiated the diagnosis in every detail.

SEVERE ACUTE MASTOIDITIS

Every case of severe acute mastoiditis has given distinct evidence on the skiagram. The changes varied from filling of the mastoid cells with something other than air (serum, pus or granulations), with indistinctness and partial disappearance of cell outlines, to circumscribed abscess formation or diffuse loss of structure of the mastoid.

CASE 4.—Mrs. S. gave a history of a running ear following an attack of influenza. Discharge continued two weeks and then stopped. Two weeks later, or four weeks after the onset, the patient came under medical observation because of pain over the mastoid, especially right. Examination revealed a thickened drum, no discharge, no perforation, marked tenderness over mastoid, but no redness or swelling. Temperature was 99 to 100; x-ray examination revealed a hazy mastoid whose cells were no longer air-filled and septa partially broken down. Operation the day following the x-ray examination verified the skiagram.

CASE 5.—Miss W., aged 25, had had influenza three weeks previously with a running ear, but without pain or tenderness over the mastoid. Discharge continued for three weeks, and patient finally sought medical attention because of an increasing malaise. Examination revealed a large perforation in posterior part of drum, with scant or no discharge. There was no swelling or redness over the mastoid, but marked tenderness on deep pressure over antrum, no fever. X-ray examination revealed a small abscess in the mastoid about the size of a hazel-nut. The rest of the mastoid appeared hazy and indistinct. Subsequent operation verified this finding in every detail.

The following case is typical of a number of cases observed from the onset, in which there were definite signs of severe mastoid involvement, but in which the operative indications were not clear. Operative interference is often delayed in these cases awaiting a spontaneous resolution. The x-ray plate showing the amount of destruction may be a deciding factor.

CASE 6.—Miss H., a nurse at Cincinnati General Hospital, aged 30, developed, incident to influenza, intense pain in the ear, which in a few hours was followed by rupture of the drum, and a profuse bloody discharge. Three days later the staff otologist was called to see her because of pain and tenderness over the mastoid. He found a small perforation and enlarged it by incision. Tenderness and pain abated, and it was thought that recovery would follow in a few days. Seven days later there was a recurrence of the pain and paracentesis of the drum was again performed. The pain and tenderness now persisted in moderate degree, and a week later I was asked to make a skiagram. The skiagram showed absolutely positive evidence of a breaking down of the entire mastoid, and the operation the following day, almost three weeks after the onset, verified the x-ray finding.

MILD ACUTE MASTOIDITIS
